## MBM29PL12LM 10

### DESCRIPTION

The MBM29PL12LM is a 128M-bit, 3.0 V-only Flash memory organized as 16M bytes by 8 bits or 8M words by 16 bits. The MBM29PL12LM is offered in 58-pin TSOP (1) and 80-ball FBGA. The device is designed to be programmed in-system with the standard 3.0 V  $V_{CC}$  supply. 12.0 V  $V_{PP}$  and 5.0 V  $V_{CC}$  are not required for write or erase operations. The devices can also be reprogrammed in standard EPROM programmers.

*(Continued)*

### PRODUCT LINE UP

Part No.	MBM29PL12LM
$V_{CC}$	3.0 V to 3.6 V
Max Address Access Time	100 ns
Max $\overline{CE}$ Access Time	100 ns
Max Page Read Access Time	30 ns

Notes : • Programming in byte mode ( × 8 ) is prohibited.  
 • Programming to the address that already contains data is prohibited.  
 (It is mandatory to erase data prior to overprogram on the same address.)

### PACKAGES

\* : MirrorFlash™ is a trademark of Fujitsu Limited.

# MBM29PL12LM<sub>10</sub>

*(Continued)*

The standard MBM29PL12LM offers access times of 90 ns, allowing operation of high-speed microprocessors without wait states. To eliminate bus contention the devices have separate chip enable ( $\overline{CE}$ ), write enable ( $\overline{WE}$ ), and output enable ( $\overline{OE}$ ) controls.

The MBM29PL12LM supports command set compatible with JEDEC single-power-supply EEPROMS standard. Commands are written into the command register. The register contents serve as input to an internal state-machine which controls the erase and programming circuitry. Write cycles also internally latch addresses and data needed for the programming and erase operations. Reading data out of the devices is similar to reading from 5.0 V and 12.0 V Flash or EPROM devices.

The MBM29PL12LM is programmed by executing the program command sequence. This will invoke the Embedded Program Algorithm™ which is an internal algorithm that automatically times the program pulse widths and verifies proper cell margin. Erase is accomplished by executing the erase command sequence. This will invoke the Embedded Erase Algorithm™ which is an internal algorithm that automatically preprograms the array if it is not already programmed before executing the erase operation. During erase, the device automatically times the erase pulse widths and verifies proper cell margin.

The device also features a sector erase architecture. The sector mode allows each sector to be erased and reprogrammed without affecting other sectors. All sectors are erased when shipped from the factory.

The device features single 3.0 V power supply operation for both read and write functions. Internally generated and regulated voltages are provided for the program and erase operations. A low  $V_{CC}$  detector automatically inhibits write operations on the loss of power. The end of program or erase is detected by Data Polling of  $DQ_7$ , by the Toggle Bit feature on  $DQ_6$ . Once the end of a program or erase cycle has been completed, the devices internally return to the read mode.

Fujitsu Flash technology combines years of Flash memory manufacturing experience to produce the highest levels of quality, reliability, and cost effectiveness. The devices electrically erase all bits within a sector simultaneously via hot-hole assisted erase. The words are programmed one word at a time using the EPROM programming mechanism of hot electron injection.

## ■ FEATURES

- **0.23  $\mu$ m Process Technology**
- **Single 3.0 V read, program and erase**  
Minimizes system level power requirements
- **Industry-standard pinouts**  
56-pin TSOP (1)  
80-ball FBGA (Package suffix: PBT)
- **Minimum 100,000 program/erase cycles**
- **High performance Page mode**  
Fast 8 bytes / 4 words access capability
- **Sector erase architecture**  
256  $\times$  64K byte and 32K word sectors  
Any combination of sectors can be concurrently erased. Also supports full chip erase
- **HiddenROM**  
256 bytes / 128 words of HiddenROM, accessible through a “HiddenROM Entry” command sequence  
Factory serialized and protected to provide a secure electronic serial number (ESN)
- **WP/ACC input pin**  
At  $V_{IL}$ , allows protection of outermost two 8K bytes / 4K words sectors, regardless of sector protection/unprotection status  
At  $V_{ACC}$ , increases program performance
- **Embedded Erase<sup>TM\*</sup> Algorithms**  
Automatically pre-programs and erases the chip or any sector
- **Embedded Program<sup>TM\*</sup> Algorithms**  
Automatically writes and verifies data at specified address
- **Data Polling and Toggle Bit feature for detection of program or erase cycle completion**
- **Ready/Busy output (RY/BY)**  
Hardware method for detection of program or erase cycle completion
- **Automatic sleep mode**  
When addresses remain stable, automatically switches themselves to low power mode
- **Erase Suspend/Resume**  
Suspends the erase operation to allow a read data and/or program in another sector within the same device
- **Low  $V_{CC}$  write inhibit  $\leq 2.5$  V**
- **Sector Group Protection**  
Hardware method disables any combination of sector groups from program or erase operations
- **Sector Group Protection Set function by Extended sector protect command**
- **Fast Programming Function by Extended Command**
- **Temporary sector group unprotection**  
Temporary sector group unprotection via the  $\overline{RESET}$  pin  
This feature allows code changes in previously locked sectors
- **In accordance with CFI (Common Flash Memory Interface)**

(Continued)

# MBM29PL12LM<sub>10</sub>

(Continued)

**Legend** : Address bits  $A_{22}$  to  $A_{15} = X = \text{“H”}$  or  $\text{“L”}$  for all address commands except for Program Address (PA), Sector Address (SA) and Sector Group Address (SGA).  
Bus operations are defined in “MBM29PL12LM User Bus Operations (Word Mode : BYTE =  $V_{IH}$ )” and “MBM29PL12LM User Bus Operations (Byte Mode : BYTE =  $V_{IL}$ )”.

RA = Address of the memory location to be read.  
PA = Address of the memory location to be programmed. Addresses are latched on the falling edge of the write pulse.  
SA = Address of the sector to be programmed / erased. The combination of  $A_{22}$ ,  $A_{21}$ ,  $A_{20}$ ,  $A_{19}$ ,  $A_{18}$ ,  $A_{17}$ ,  $A_{16}$ , and  $A_{15}$  will uniquely select any sector. See “Sector Address Table (MBM29PL12LM)”.

SGA = Sector Group Address to be protected. See “Sector Group Address Table (MBM29PL12LM)”.

RD = Data read from location RA during read operation.  
PD = Data to be programmed at location PA. Data is latched on the rising edge of write plus.  
WBL = Write Buffer Location  
HRA = Address of the HiddenROM area ;  
Word Mode : 000000h to 000007h  
Byte Mode : 000000h to 0000FFh

- \*1 : The command combinations not described in “MBM29PL12LM Standard Command Definitions” are illegal.
- \*2 : Both of these reset commands are equivalent except for "Write to Buffer Abort Reset".
- \*3 : The Erase Suspend and Erase Resume command are valid only during a sector erase operation.
- \*4 : The Set to Fast Mode command is required prior to the Fast Program command.
- \*5 : The Reset from Fast Mode command is required to return to the read mode when the device is in fast mode.
- \*6 : Reset to the read mode. The Write to Buffer Abort Reset command is required after the Write to Buffer operation was aborted.
- \*7 : This command is valid while  $\overline{\text{RESET}} = V_{ID}$ .
- \*8 : Sector Group Address (SGA) with  $A_6 = 0$ ,  $A_3 = 0$ ,  $A_2 = 0$ ,  $A_1 = 1$ , and  $A_0 = 0$
- \*9 : The valid address are  $A_6$  to  $A_0$ .
- \*10 : The HiddenROM Entry command is required prior to the HiddenROM programming.
- \*11 : This command is valid during HiddenROM mode.
- \*12 : The data “F0h” is also acceptable.
- \*13 : Indicates read cycle.

## Sector Group Protection Verify Autoselect Codes

Type		A <sub>22</sub> to A <sub>15</sub>	A <sub>6</sub>	A <sub>3</sub>	A <sub>2</sub>	A <sub>1</sub>	A <sub>0</sub>	A <sub>-1</sub> *1	Code (HEX)
Manufacturer's Code		X	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IL</sub>	04h
Device Code	Word	X	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IH</sub>	X	227Eh
	Byte							V <sub>IL</sub>	7Eh
Extended Device Code*2	Word	X	V <sub>IL</sub>	V <sub>IH</sub>	V <sub>IH</sub>	V <sub>IH</sub>	V <sub>IL</sub>	X	2212h
	Byte							V <sub>IL</sub>	12h
	Word	X	V <sub>IL</sub>	V <sub>IH</sub>	V <sub>IH</sub>	V <sub>IH</sub>	V <sub>IH</sub>	X	2200h
	Byte							V <sub>IL</sub>	00h
Sector Group Protection*4		Sector Group Addresses	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IH</sub>	V <sub>IL</sub>	V <sub>IL</sub>	*3

\*1 : A<sub>-1</sub> is for Byte mode.

\*2 : At Word mode, a read cycle at address 01h ( at Byte mode, 02h ) outputs device code. When 227Eh ( at Byte mode, 7Eh ) is output, it indicates that reading two additional codes, called Extended Device Codes, will be required. Therefore the system may continue reading out these Extended Device Codes at the address of 0Eh ( at Byte mode, 1Ch ), as well as at 0Fh ( at Byte mode, 1Eh ).

\*3 : Outputs 01h at protected sector group addresses and outputs 00h at unprotected sector group addresses.

\*4 : At  $\overline{CE} = \text{Fix}$ , designate SGA as (A<sub>6</sub>, A<sub>3</sub>, A<sub>2</sub>, A<sub>1</sub>, A<sub>0</sub>) = (0, 0, 0, 1, 0) , with an interval of one cycle after  $\overline{WE}$  rising (the last write command) .

50h	01h	Program Suspend (01h = Supported)

## ■ FUNCTIONAL DESCRIPTION

### Standby Mode

There are two ways to implement the standby mode on the device, one using both the  $\overline{CE}$  and  $\overline{RESET}$  pins, and the other via the  $\overline{RESET}$  pin only.

When using both pins, CMOS standby mode is achieved with  $\overline{CE}$  and  $\overline{RESET}$  input held at  $V_{CC} \pm 0.3$  V. Under this condition the current consumed is less than 5  $\mu$ A Max. During Embedded Algorithm operation,  $V_{CC}$  active current ( $I_{CC2}$ ) is required even when  $\overline{CE} = "H"$ . The device can be read with standard access time ( $t_{CE}$ ) from either of these standby modes.

When using the  $\overline{RESET}$  pin only, CMOS standby mode is achieved with  $\overline{RESET}$  input held at  $V_{SS} \pm 0.3$  V ( $\overline{CE} = "H"$  or "L"). Under this condition the current consumed is less than 5  $\mu$ A Max. Once the  $\overline{RESET}$  pin is set high, the device requires  $t_{RH}$  as a wake-up time for output to be valid for read access.

During standby mode, the output is in the high impedance state, regardless of  $\overline{OE}$  input.

### Automatic Sleep Mode

Automatic sleep mode works to restrain power consumption during read-out of device data. It can be useful in applications such as handy terminal, which requires low power consumption.

To activate this mode, the device automatically switch themselves to low power mode when the device addresses remain stable after 30 ns from data valid. It is not necessary to control  $\overline{CE}$ ,  $\overline{WE}$ , and  $\overline{OE}$  in this mode. The current consumed is typically 1  $\mu$ A (CMOS Level).

Since the data are latched during this mode, the data are continuously read out. When the addresses are changed, the mode is automatically canceled and the device read-out the data for changed addresses.

### Autoselect

The Autoselect mode allows reading out of a binary code and identifies its manufacturer and type. It is intended for use by programming equipment for the purpose of automatically matching the device to be programmed with its corresponding programming algorithm.

To activate this mode, the programming equipment must force  $V_{ID}$  on address pin  $A_9$ . Three identifier bytes may then be sequenced from the devices outputs by toggling  $A_0$ . All addresses can be either High or Low except  $A_6$ ,  $A_3$ ,  $A_2$ ,  $A_1$  and  $A_0$ . See "MBM29PL12LM User Bus Operations (Word Mode :  $\overline{BYTE} = V_{IH}$ )" and "MBM29PL12LM User Bus Operations (Byte Mode :  $\overline{BYTE} = V_{IL}$ )" in ■DEVICE BUS OPERATION.

The manufacturer and device codes may also be read via the command register, for instances when the device is erased or programmed in a system without access to high voltage on the  $A_9$  pin. The command sequence is illustrated in "MBM29PL12LM Standard Command Definitions" in ■DEVICE BUS OPERATION. Refer to Autoselect Command section.

In Word mode, a read cycle from address 00h returns the manufacturer's code (Fujitsu = 04h) . A read cycle at address 01h outputs device code. When 227Eh is output, it indicates that two additional codes, called Extended Device Codes will be required. Therefore the system may continue reading out these Extended Device Codes at addresses of 0Eh and 0Fh. Notice that the above applies to Word mode. The addresses and codes differ from those of Byte mode. Refer to "Sector Group Protection Verify Autoselect Codes" in ■DEVICE BUS OPERATION.

### Read Mode

The device has two control functions required to obtain data at the outputs.  $\overline{CE}$  is the power control and used for a device selection.  $\overline{OE}$  is the output control and used to gate data to the output pins.

Address access time ( $t_{ACC}$ ) is equal to the delay from stable addresses to valid output data. The chip enable access time ( $t_{CE}$ ) is the delay from stable addresses and stable  $\overline{CE}$  to valid data at the output pins. The output enable access time ( $t_{OE}$ ) is the delay from the falling edge of  $\overline{OE}$  to valid data at the output pins. (Assuming the addresses have been stable for at least  $t_{ACC} - t_{OE}$  time.) When reading out a data without changing addresses after power-up, to input hardware reset or to change  $\overline{CE}$  pin from "H" or "L".

## Page Mode Read

The device is capable of fast read access for random locations within limited address location called page. The page size of the device is 8 bytes / 4 words, within the appropriate page being selected by the higher address bits  $A_{22}$  to  $A_2$  and the address bits  $A_1$  to  $A_0$  in Word mode ( $A_1$  to  $A_{-1}$  in Byte mode) determining the specific word within that page. This is an asynchronous operation with the microprocessor supplying the specific word location.

The initial page access is equal to the random access ( $t_{ACC}$ ) and subsequent Page read access (as long as the locations specified by the microprocessor fall within that Page) is equivalent to the page address access time ( $t_{PACC}$ ). Here again,  $\overline{CE}$  selects the device and  $\overline{OE}$  is the output control and should be used to gate data to the output pins if the device is selected. Fast Page mode, accesses are obtained by keeping  $A_{20}$  to  $A_2$  constant and changing  $A_1$  and  $A_0$  in Word mode ( $A_1$  to  $A_{-1}$  in Byte mode) to select the specific word within that Page.

Refer to “Read Operation Timing Diagram” in ■TIMING DIAGRAM.

## Output Disable

With the  $\overline{OE}$  input at logic high level ( $V_{IH}$ ), output from the devices are disabled. This may cause the output pins to be in a high impedance state.

## Write

Device erasure and programming are accomplished via the command register. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the device function.

The command register itself does not occupy any addressable memory location. The register is a latch used to store the commands, along with the address and data information needed to execute the command. The command register is written by bringing  $\overline{WE}$  to  $V_{IL}$ , while  $\overline{CE}$  is at  $V_{IL}$  and  $\overline{OE}$  is at  $V_{IH}$ . Addresses are latched on the falling edge of  $\overline{WE}$  or  $\overline{CE}$ , whichever starts later; while data is latched on the rising edge of  $\overline{WE}$  or  $\overline{CE}$ , whichever starts first. Standard microprocessor write timings are used.

Refer to AC Write Characteristics and the Erase/Programming Waveforms for specific timing parameters.

## Sector Group Protection

The device features hardware sector group protection. This feature will disable both program and erase operations in any combination of 70 sector groups of memory. See “Sector Group Address Table (MBM29PL12LM)” in ■DEVICE BUS OPERATION. The user’s side can use the sector group protection using programming equipment. The device is shipped with all sector groups that are unprotected.

To activate it, the programming equipment must force  $V_{ID}$  on address pin  $A_9$  and control pin  $\overline{OE}$ ,  $\overline{CE} = V_{IL}$  and  $(A_6, A_3, A_2, A_1, A_0) = (0, 0, 0, 1, 0)$ . The sector group addresses ( $A_{22}, A_{21}, A_{20}, A_{19}, A_{18}, A_{17}, A_{16}$ , and  $A_{15}$ ) should be set to the sector to be protected. “Sector Group Address Table (MBM29PL12LM)” in ■DEVICE BUS OPERATION defines the sector address for each of the 70 individual sectors, and “Sector Group Address Table (MBM29PL12LM)” in ■DEVICE BUS OPERATION defines the sector group address for each of the twenty-four (24) individual group sectors. Programming of the protection circuitry begins on the falling edge of the  $\overline{WE}$  pulse and is terminated with the rising edge of the same. Sector group addresses must be held constant during the  $\overline{WE}$  pulse. See “Sector Group Protection Timing Diagram” in ■TIMING DIAGRAM and “Sector Group Protection Algorithm” in ■FLOW CHART for sector group protection timing diagram and algorithm.

To verify programming of the protection circuitry, the programming equipment must force  $V_{ID}$  on address pin  $A_9$  with  $\overline{CE}$  and  $\overline{OE}$  at  $V_{IL}$  and  $\overline{WE}$  at  $V_{IH}$ . Scanning the sector group addresses ( $A_{22}, A_{21}, A_{20}, A_{19}, A_{18}, A_{17}, A_{16}$ , and  $A_{15}$ ) while  $(A_6, A_3, A_2, A_1, A_0) = (0, 0, 0, 1, 0)$  will produce a logical “1” code at device output  $DQ_0$  for a protected sector. Otherwise the device will produce “0” for unprotected sectors. In this mode, the lower order addresses, except for  $A_0, A_1, A_2, A_3$ , and  $A_6$  can be either High or Low. Address locations with  $A_1 = V_{IL}$  are reserved for Autoselect manufacturer and device codes.  $A_{-1}$  requires applying to  $V_{IL}$  on Byte mode.

It is also possible to determine if a sector group is protected in the system by writing an Autoselect command. Performing a read operation at the address location  $XX02h$ , where the higher order addresses ( $A_{22}, A_{21}, A_{20}, A_{19}, A_{18}, A_{17}, A_{16}$ , and  $A_{15}$ ) are the desired sector group address will produce a logical “1” at  $DQ_0$  for a protected sector group. See “MBM29PL12LM User Bus Operations (Word Mode :  $\overline{BYTE} = V_{IH}$ )” and “Sector Group Protection Verify Autoselect Codes” in ■DEVICE BUS OPERATION for Autoselect codes.

## Temporary Sector Group Unprotection

This feature allows temporary unprotection of previously protected sector groups of the devices in order to change data. The Sector Group Unprotection mode is activated by setting the  $\overline{\text{RESET}}$  pin to high voltage ( $V_{\text{ID}}$ ). During this mode, formerly protected sector groups can be programmed or erased by selecting the sector group addresses. Once the  $V_{\text{D}}$  is taken away from the  $\overline{\text{RESET}}$  pin, all the previously protected sector groups will be protected again. Refer to “Temporary Sector Group Unprotection Timing Diagram” in ■TIMING DIAGRAM and “Temporary Sector Group Unprotection Algorithm” in ■FLOW CHART.

## Hardware Reset

The devices may be reset by driving the  $\overline{\text{RESET}}$  pin to  $V_{\text{IL}}$  from  $V_{\text{IH}}$ . The  $\overline{\text{RESET}}$  pin has a pulse requirement and has to be kept low ( $V_{\text{IL}}$ ) for at least “ $t_{\text{RP}}$ ” in order to properly reset the internal state machine. Any operation in the process of being executed will be terminated and the internal state machine will be reset to the read mode “ $t_{\text{READY}}$ ” after the  $\overline{\text{RESET}}$  pin is driven low. When the  $\overline{\text{RESET}}$  pin is low, the devices will be in the standby mode for the duration of the pulse and all the data output pins will be tri-stated. If a hardware reset occurs during a program or erase operation, the data at that particular location will be corrupted.

Furthermore, once the  $\overline{\text{RESET}}$  pin goes high, the devices require an additional “ $t_{\text{RH}}$ ” before it will allow read access.

## Write Protect ( $\overline{\text{WP}}$ )

The Write Protection function provides a hardware method of protecting certain first 64K bytes / 32K words sector without using  $V_{\text{D}}$ . This function is one of two provided by the  $\overline{\text{WP/ACC}}$  pin.

If the system asserts  $V_{\text{IL}}$  on the  $\overline{\text{WP/ACC}}$  pin, the device disables program and erase functions in the first 64K bytes / 32K words sector independently of whether this sector was protected or unprotected using the method described in “Sector Group Protection” above.

If the system asserts  $V_{\text{IH}}$  on the  $\overline{\text{WP/ACC}}$  pin, the device reverts of whether the first 64K bytes / 32K words sectors were last set to be protected to the unprotected status. Sector protection or unprotection for this sector depends on whether this was last protected or unprotected using the method described in “Sector protection/unprotection”.

## Accelerated Program Operation

The device offers accelerated program operation which enables programming in high speed. If the system asserts  $V_{\text{ACC}}$  to the  $\overline{\text{WP/ACC}}$  pin, the device automatically enters the acceleration mode and the time required for program operation will reduce to about 85%. This function is primarily intended to allow high speed programming, so caution is needed as the sector group becomes temporarily unprotected.

The system would use a fast program command sequence when programming during acceleration mode. Set command to fast mode and reset command from fast mode are not necessary. When the device enters the acceleration mode, the device is automatically set to fast mode. Therefore, the present command and sequence could be used for programming and detection of completion during acceleration mode.

Removing  $V_{\text{ACC}}$  from the  $\overline{\text{WP/ACC}}$  pin returns the device to normal operation. Do not remove  $V_{\text{ACC}}$  from the  $\overline{\text{WP/ACC}}$  pin while programming. See “Accelerated Program Timing Diagram” in ■TIMING DIAGRAM.

## $V_{\text{CCQ}}$

$V_{\text{CCQ}}$  determines the MBM29PL12LM voltage output.  $V_{\text{CCQ}}$  facilitates signal exchange within devices that operate in different voltage.

## ■ COMMAND DEFINITIONS

Device operations are selected by writing specific address and data sequences into the command register. “MBM29PL12LM Standard Command Definitions” in ■DEVICE BUS OPERATION shows the valid register command sequences. Note that the Erase Suspend (B0h) and Erase Resume (30h) commands are valid only while the Sector Erase operation is in progress. Also the Program Suspend (B0h) and Program Resume (30h) commands are valid only while the program operation is in progress. Moreover reset commands are functionally equivalent. Please note that commands must be asserted to DQ<sub>7</sub> to DQ<sub>0</sub> and DQ<sub>15</sub> to DQ<sub>8</sub> bits are ignored.

### Reset Command

In order to return from Autoselect mode or Exceeded Timing Limits (DQ<sub>5</sub> = 1) to Read mode, the Reset operation is initiated by writing the reset command sequence into the command register. The devices remain enabled for reads until the command register contents are altered.

The devices will automatically be in the reset state after power-up. In this case, a command sequence is not required in order to read data.

### Autoselect Command

Flash memories are intended for use in applications where the local CPU alters memory contents. Therefore, manufacture and device codes must be accessible while the devices reside in the target system. PROM programmers typically access the signature codes by raising A<sub>9</sub> to a high voltage. However applying high voltage onto the address lines is not generally desired system design practice.

The device contains an Autoselect command operation to supplement traditional PROM programming methodology. The operation is initiated by writing the Autoselect command sequence into the command register.

The Autoselect command sequence is initiated first by writing two unlock cycles. This is followed by a third write cycle that contains the address and the Autoselect command. Then the manufacture and device codes can be read from the address, and an actual data of memory cell can be read from the another address.

Following the command write, a read cycle from address 00h returns the manufactures's code (Fujitsu = 04h). A read cycle at address 01h outputs device code. When 227Eh is output, it indicates that two additional codes, called Extended Device Codes will be required. Therefore the system may continue reading out these Extended Device Codes at address of 0Eh as well as at 0Fh. Notice that above applies to Word mode. The addresses and codes differ from those of Byte mode. Refer to “Sector Group Protection Verify Autoselect Codes” in ■DEVICE BUS OPERATION.

To terminate the operation, it is necessary to write the reset command into the register. To execute the Autoselect command during the operation, reset command must be written before the Autoselect command.

### Programming

The devices are programmed on a word-by-word basis. Programming is a 4 bus cycle operation. There are two “unlock” write cycles. These are followed by the program set-up command and data write cycles. Addresses are latched on the falling edge of  $\overline{CE}$  or  $\overline{WE}$ , whichever happens later and the data is latched on the rising edge of  $\overline{CE}$  or  $\overline{WE}$ , whichever happens first. The rising edge of the last  $\overline{CE}$  or  $\overline{WE}$  (whichever happens first) starts programming. Upon executing the Embedded Program Algorithm command sequence, the system is not required to provide further controls. The device will automatically provide adequate internally generated program pulses and verify the programmed cell margin.

The system can determine the status of the program operation by using DQ<sub>7</sub> ( $\overline{\text{Data Polling}}$ ), DQ<sub>6</sub> (Toggle Bit) or RY/BY. The Data Polling and Toggle Bit are automatically performed at the memory location being programmed.

The programming operation is completed when the data on DQ<sub>7</sub> is equivalent to data written to this bit at which the devices return to the read mode and program addresses are no longer latched. Therefore, the devices require that a valid address to the devices be supplied by the system at this particular instance. Hence  $\overline{\text{Data Polling}}$  requires the same address which is being programmed.

If hardware reset occurs during the programming operation, the data being written is not guaranteed.

Programming is allowed in any address sequence and across sector boundaries. Beware that a data “0” cannot be programmed back to a “1”. Attempting to do so may result in either failure condition or an apparent success according to the data polling algorithm. But a read from reset command will show that the data is still “0”. Only erase operations can convert “0”s to “1”s.

Note that attempting to program a “1” over a “0” will result in programming failure. This precaution is the same with Fujitsu standard NOR devices. “Embedded Program™ Algorithm” in ■FLOW CHART illustrates the Embedded Program™ Algorithm using typical command strings and bus operations.

## Program Suspend/Resume

The Program Suspend command allows the system to interrupt a program operation so that data can be read from any address. Writing the Program Suspend command (B0h) during Embedded Program operation immediately suspends the programming. Refer to "Erase Suspend/Resume" for the detail.

When the Program Suspend command is written during a programming process, the chip halts the program operation within 1 $\mu$ s and suspend the status bits. After the program operation has been suspended, the system can read data from any address. Normal read timing and command definitions apply. The data at program-suspended address is not valid.

After the Program Resume command (30h) is written, the chip reverts to programming. The system can determine the status of the program operation using the DQ<sub>7</sub> or DQ<sub>6</sub> status bits, just as in the standard program operation. See "Write Operation Status" for more information.

When issuing program suspend command in 4  $\mu$ s after issuing program command, determine the status of program operation by reading status bit at more 4  $\mu$ s after issuing program resume command.

The system also writes the Autoselect command sequence in the Program Suspend mode. The device allows reading Autoselect codes at the addresses within programming sectors, since the codes are not stored in the memory. When the device exits the Autoselect mode, the device reverts to the Program Suspend mode, and is ready for another valid operation. See "Autoselect Command Sequence" for more information.

The system must write the Program Resume command to exit from the Program Suspend mode and continue the programming operation. Further writes of the Resume command are ignored. Another Program Suspend command can be written after the chip resumes programming.

## Write Buffer Programming Operations

Write Buffer Programming allows the system write to series of 16 words in one programming operation. This results in faster effective word programming time than the standard programming algorithms. The Write Buffer Programming command sequence is initialized by first writing two unlock cycles. This is followed by a third write cycle selecting the Sector Address in which programming will occur. In fourth cycle contains both Sector Address and unique code for data bus width will be loaded into the page buffer at the Sector Address in which programming will occur.

The system then writes the starting address/data combination. This “starting address” must be the same Sector Address used in third and fourth cycles and its lower addresses of A<sub>3</sub> to A<sub>0</sub> should be 0h. All subsequent address must be incremented by 000Fh. Addresses are latched on the falling edge of CE or WE, whichever happens later and the data is latched on the rising edge of CE or WE, whichever happens first. The rising edge of the last CE or WE (whichever happens first) starts programming. Upon executing the Write Buffer Programming Operations command sequence, the system is not required to provide further controls. The device will automatically provide adequate internally generated program pulses and verify the programmed cell margin.

DQ<sub>7</sub>(Data Polling), DQ<sub>6</sub>(Toggle Bit), DQ<sub>5</sub>(Exceeded Timing Limits), DQ<sub>1</sub>(Write-to-Buffer Abort) should be monitored to determine the device status during Write Buffer Programming. In addition to these functions, it is also possible to indicate to the host system that Write Buffer Programming Operations are either in progress or have been completed by RY/BY. See “Hardware Sequence Flags”.

The  $\overline{\text{Data}}$  polling techniques described in “ $\overline{\text{Data}}$  Polling Algorithm” in ■FLOW CHART should be used while monitoring the last address location loaded into the write buffer. In addition, it is not necessary to specify an address in Toggle Bit techniques described in “Toggle Bit Algorithm” in ■FLOW CHART. The automatic pro-

programming operation is completed when the data on DQ<sub>7</sub> is equivalent to the data written to this bit at which time the device returns to the read mode ( See "Hardware Sequence Flags").

The write-buffer programming operation can be suspended/resumed using the standard program suspend/resume commands.

Once the write buffer programming is set, the system must then write the "Program Buffer to Flash" command at the Sector Address. Any other address/data combination will abort the Write Buffer Programming operation and the device will continue busy state.

The Write Buffer Programming Sequence can be ABORTED by doing the following :

- Different Sector Address is asserted.
- Write data other than the "Program Buffer to Flash" command after the specified number of "data load" cycles.

A "Write-to-Buffer-Abort Reset" command sequence must be written to the device to return to read mode. (See "MBM29PL12LM Standard Command Definitions" in ■DEVICE BUS OPERATION for details on this command sequence.)

## Chip Erase

Chip erase is a 6 bus cycle operation. It begins two "unlock" write cycles followed by writing the "set-up" command, and two "unlock" write cycles followed by the chip erase command which invokes the Embedded Erase algorithm.

The device does not require the user to program the device prior to erase. Upon executing the Embedded Erase Algorithm the devices automatically programs and verifies the entire memory for an all 0 data pattern prior to electrical erase (Preprogram function). The system is not required to provide any controls or timings during these operations.

The system can determine the erase operation status by using DQ<sub>7</sub> ( $\overline{\text{Data}}$  Polling), DQ<sub>6</sub> (Toggle Bit) and DQ<sub>2</sub> (Toggle Bit II) or RY/ $\overline{\text{BY}}$  output signal. The chip erase begins on the rising edge of the last  $\overline{\text{CE}}$  or  $\overline{\text{WE}}$ , whichever happens first from last command sequence and completes when the data on DQ<sub>7</sub> is "1" at which time the device returns to read mode.

## Sector Erase

Sector erase is a 6 bus cycle operation. There are two "unlock" write cycles. These are followed by writing the "set-up" command. Two more "unlock" write cycles are then followed by the Sector Erase command.

Multiple sectors may be erased concurrently by writing the same six bus cycle operations. This sequence is followed by writes of the Sector Erase command to addresses in other sectors desired to be concurrently erased. The time between writes must be less than Erase Time-out time( $t_{\text{row}}$ ). Otherwise that command will not be accepted and erasure will not start. It is recommended that processor interrupts be disabled during this time to guarantee this condition. The interrupts can reoccur after the last Sector Erase command is written. A time-out of " $t_{\text{row}}$ " from the rising edge of last  $\overline{\text{CE}}$  or  $\overline{\text{WE}}$ , whichever happens first, will initiate the execution of the Sector Erase command(s). If another falling edge of  $\overline{\text{CE}}$  or  $\overline{\text{WE}}$ , whichever happens first occurs within the " $t_{\text{row}}$ " time-out window the timer is reset (monitor DQ<sub>3</sub> to determine if the sector erase timer window is still open, see section DQ<sub>3</sub>, Sector Erase Timer). Resetting the devices once execution has begun will corrupt the data in the sector. In that case, restart the erase on those sectors and allow them to complete (refer to the Write Operation Status). Loading the sector erase buffer may be done in any sequence and with any number of sectors (0 to 255).

Sector erase does not require the user to program the devices prior to erase. The devices automatically program all memory locations in the sector(s) to be erased prior to electrical erase using the Embedded Erase Algorithm. When erasing a sector, the remaining unselected sectors remain unaffected. The system is not required to provide any controls or timings during these operations.

The system can determine the status of the erase operation by using DQ<sub>7</sub> ( $\overline{\text{Data}}$  Polling), DQ<sub>6</sub> (Toggle Bit) or RY/ $\overline{\text{BY}}$ .

The sector erase begins after the " $t_{\text{row}}$ " time-out from the rising edge of  $\overline{\text{CE}}$  or  $\overline{\text{WE}}$  whichever happens first for the last sector erase command pulse and completes when the data on DQ<sub>7</sub> is "1" (see Write Operation Status section), at which the devices return to the read mode.  $\overline{\text{Data}}$  polling and Toggle Bit must be performed at an address within any of the sectors being erased.

### Erase Suspend/Resume

The Erase Suspend command allows the user to interrupt Sector Erase operation and then perform read to a sector not being erased. This command is applicable ONLY during the Sector Erase operation within the time-out period for sector erase. Writing the Erase Suspend command (B0h) during the Sector Erase time-out results in immediate termination of the time-out period and suspension of the erase operation.

Writing the "Erase Resume" command resumes the erase operation.

When the "Erase Suspend" command is written during the Sector Erase operation, the device takes maximum of "t<sub>SPD</sub>" to suspend the erase operation. When the devices enter the erase-suspended mode, the RY/ $\overline{\text{BY}}$  output pin will be at High-Z and the DQ<sub>7</sub> bit will be at logic "1" and DQ<sub>6</sub> will stop toggling. The user must use the address of the erasing sector for reading DQ<sub>6</sub> and DQ<sub>7</sub> to determine if the erase operation has been suspended. Further writes of the Erase Suspend command are ignored.

When the erase operation is suspended, the devices default to the erase-suspend-read mode. Reading data in this mode is the same as reading from the standard read mode, except that the data must be read from sectors that have not been erase-suspended. Reading successively from the erase-suspended sector while the device is in the erase-suspend-read mode will cause DQ<sub>2</sub> to toggle. See the section on DQ<sub>2</sub>.

To resume the operation of Sector Erase, the Resume command (30h) should be written. Any further writes of the Resume command at this point will be ignored. Another Erase Suspend command can be written after the chip has resumed erasing.

Do not issue program command after entering erase-suspend-read mode.

### Fast Mode Set/Reset

The device has Fast Mode function. It dispenses with the initial two unlock cycles required in the standard program command sequence by writing Fast Mode command into the command register. In this mode, the required bus cycle for programming consists of two cycles instead of 4 bus cycles in standard program command. The read operation is also executed after exiting this mode. During the Fast mode, do not write any command other than the Fast program/Fast mode reset command. To exit from this mode, write Fast Mode Reset command into the command register. (Refer to the "Embedded Program™ Algorithm for Fast Mode" in ■FLOW CHART.) The V<sub>CC</sub> active current is required even  $\overline{\text{CE}} = V_{\text{IH}}$  during Fast Mode.

### Fast Programming

During Fast Mode, the programming can be executed with 2 bus cycles operation. The Embedded Program Algorithm is executed by writing program set-up command (A0h) and data write cycles (PA/PD). See "Embedded Program™ Algorithm for Fast Mode" in ■FLOW CHART.

## Extended Sector Group Protection

In addition to normal sector group protection, the device has Extended Sector Group Protection as extended function. This function enables protection of the sector group by forcing  $V_{ID}$  on  $\overline{RESET}$  pin and writes a command sequence. Unlike conventional procedures, it is not necessary to force  $V_{ID}$  and control timing for control pins. The only  $\overline{RESET}$  pin requires  $V_{ID}$  for sector group protection in this mode. The extended sector group protection requires  $V_{ID}$  on  $\overline{RESET}$  pin. With this condition, the operation is initiated by writing the set-up command (60h) into the command register. Then the sector group addresses pins ( $A_{22}, A_{21}, A_{20}, A_{19}, A_{18}, A_{17}, A_{16}$  and  $A_{15}$ ) and ( $A_6, A_3, A_2, A_1, A_0$ ) = (0, 0, 0, 1, 0) should be set to the sector group to be protected (set  $V_{IL}$  for the other addresses pins is recommended), and write extended sector group protection command (60h). A sector group is typically protected in 250  $\mu$ s. To verify programming of the protection circuitry, the sector group addresses pins ( $A_6, A_3, A_2, A_1, A_0$ ) = (0, 0, 0, 1, 0) should be set and write a command (40h). Following the command write, a logical "1" at device output  $DQ_0$  will produce for protected sector in the read operation. If the output data is logical "0", write the extended sector group protection command (60h) again. To terminate the operation, set  $\overline{RESET}$  pin to  $V_{IH}$ . (Refer to the "Extended Sector Group Protection Timing Diagram" in ■TIMING DIAGRAM and "Extended Sector Group Protection Algorithm" in ■FLOW CHART.)

## Query Command (CFI : Common Flash Memory Interface)

The CFI (Common Flash Memory Interface) specification outlines device and host system software interrogation handshake which allows specific vendor-specified software algorithms to be used for entire families of devices. This allows device-independent, JEDEC ID-independent, and forward-and backward-compatible software support for the specified flash device families. Refer to CFI specification in detail.

The operation is initiated by writing the query command (98h) into the command register. Following the command write, a read cycle from specific address retrieves device information. Please note that output data of upper byte ( $DQ_{15}$  to  $DQ_8$ ) is "0". Refer to the CFI code table. To terminate operation, it is necessary to write the Reset command sequence into the register. (See "Common Flash Memory Interface Code" in ■DEVICE BUS OPERATION.)

## HiddenROM Mode

### (1) HiddenROM Region

The HiddenROM (HiddenROM) feature provides a Flash memory region that the system may access through a new command sequence. This is primarily intended for customers who wish to use an Electronic Serial Number (ESN) in the device with the ESN protected against modification. Once the HiddenROM region is protected, any further modification of that region is impossible. This ensures the security of the ESN once the product is shipped to the field.

The HiddenROM region is 256 bytes / 128 words in length. After the system writes the HiddenROM Entry command sequence, it may read the HiddenROM region by using device addresses  $A_6$  to  $A_0$  ( $A_{22}$  to  $A_{15}$  are all "0"). That is, the device sends only program command that would normally be sent to the address to the HiddenROM region. This mode of operation continues until the system issues the Exit HiddenROM command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending commands to the address.

If you request Fujitsu to program the ESN in the device, please contact a Fujitsu representative for more information.

### (2) HiddenROM Entry Command

The device has a HiddenROM region with One Time Protect function. This area is to enter the security code and to enable the change of the code once set. Programming is allowed in this area until it is protected. However, once it gets protected, it is impossible to unprotect. Therefore, extreme caution is required.

The HiddenROM region is 256 bytes / 128 words. This area is in SA0. Therefore, write the HiddenROM entry command sequence to enter the HiddenROM region. It is called HiddenROM mode when the HiddenROM region appears.

Sectors other than the block area SA0 can be read during HiddenROM mode. Read/program of the HiddenROM region is possible during HiddenROM mode. Write the HiddenROM reset command sequence to exit the HiddenROM mode. Note that any other commands should not be issued than the HiddenROM program/protection/reset commands during the HiddenROM mode. When you issue the other commands including the suspend/resume capability, send the HiddenROM reset command first to exit the HiddenROM mode and then issue each command.

### (3) HiddenROM Program Command

To program the data to the HiddenROM region, write the HiddenROM program command sequence during HiddenROM mode. This command is the same as the usual program command, except that it needs to write the command during HiddenROM mode. Therefore the detection of completion method is the same as in the past, using the  $DQ_7$  data pooling,  $DQ_6$  Toggle bit or RY/BY. You should pay attention to the address to be programmed. If an address not in the HiddenROM region is selected, the previous data will be deleted. During the write into the HiddenROM region, the program suspend command issuance is prohibited.

### (4) HiddenROM Protect Command

There are two methods to protect the HiddenROM region. One is to write the sector group protect setup command (60h), set the sector address in the HiddenROM region and  $(A_6, A_3, A_2, A_1, A_0) = (0, 0, 0, 1, 0)$ , and write the sector group protect command (60h) during the HiddenROM mode. The same command sequence may be used because it is the same as the extension sector group protect in the past, except that it is in the HiddenROM mode and does not apply high voltage to the  $\overline{\text{RESET}}$  pin. Please refer to above mentioned "Extended Sector Group Protection" for details of sector group protect setting.

The other method is to apply high voltage ( $V_{ID}$ ) to  $A_9$  and  $\overline{\text{OE}}$ , set the sector address in the HiddenROM region and  $(A_6, A_3, A_2, A_1, A_0) = (0, 0, 0, 1, 0)$ , and apply the write pulse during the HiddenROM mode. To verify the protect circuit, apply high voltage ( $V_{ID}$ ) to  $A_9$ , specify  $(A_6, A_3, A_2, A_1, A_0) = (0, 0, 0, 1, 0)$  and the sector address in the HiddenROM region, and read. When "1" appears on  $DQ_0$ , the protect setting is completed. "0" will appear on  $DQ_0$  if it is not protected. Apply write pulse again. The same command sequence could be used for the above method because other than the HiddenROM mode, it is the same as the sector group protect previously mentioned.

# MBM29PL12LM<sub>10</sub>

Take note that other sector groups will be affected if an address other than those for the HiddenROM region is selected for the sector group address. Pay close attention that once it is protected, protection CANNOT BE CANCELLED.

## Write Operation Status

Detailed in “Hardware Sequence Flags” are all the status flags which can determine the status of the device for current mode operation. When checking Hardware Sequence Flags during program operations, it should be checked 4  $\mu$ s after issuing program command. During sector erase, the part provides the status flags automatically to the I/O ports. The information on DQ<sub>2</sub> is address sensitive. If an address from an erasing sector is consecutively read, then the DQ<sub>2</sub> bit will toggle. However DQ<sub>2</sub> will not toggle if an address from a non-erasing sector is consecutively read. This allows the user to determine which sectors are erasing.

Once erase suspend is entered address sensitivity still applies. If the address of a non-erasing sector (one available for read) is provided, then stored data can be read from the device. If the address of an erasing sector (one unavailable for read) is applied, the device will output its status bits.

### Hardware Sequence Flags

Status		DQ <sub>7</sub>	DQ <sub>6</sub>	DQ <sub>5</sub>	DQ <sub>3</sub>	DQ <sub>2</sub>	DQ <sub>1</sub> <sup>*3</sup>	
In Progress	Embedded Program Algorithm	$\overline{DQ}_7$	Toggle	0	0	1	0	
	Embedded Erase Algorithm	0	Toggle	0	1	Toggle <sup>*1</sup>	N/A	
	Program Suspend Mode	Program-Suspend-Read (Program Suspended Sector)	Data	Data	Data	Data	Data	Data
		Program-Suspend-Read (Non-Program Suspended Sector)	Data	Data	Data	Data	Data	Data
	Erase Suspend Mode	Erase-Suspend-Read (Erase Suspended Sector)	1	1	0	0	Toggle <sup>*1</sup>	N/A
		Erase-Suspend-Read (Non-Erase Suspended Sector)	Data	Data	Data	Data	Data	Data
Erase-Suspend-Program (Non-Erase Suspended Sector)		$\overline{DQ}_7$	Toggle	0	0	1 <sup>*2</sup>	N/A	
Exceeded Time Limits	Embedded Program Algorithm	$\overline{DQ}_7$	Toggle	1	0	1	N/A	
	Embedded Erase Algorithm	0	Toggle	1	1	N/A	N/A	
	Erase Suspend Mode	Erase-Suspend-Program (Non-Erase Suspended Sector)	$\overline{DQ}_7$	Toggle	1	0	N/A	N/A
Write to Buffer <sup>*4</sup>	BUSY State	$\overline{DQ}_7$	Toggle	0	N/A	N/A	0	
	Exceeded Timing Limits	$\overline{DQ}_7$	Toggle	1	N/A	N/A	0	
	ABORT State	N/A	Toggle	0	N/A	N/A	1	

\*1 : Successive reads from the erasing or erase-suspend sector will cause DQ<sub>2</sub> to toggle.

\*2 : Reading from non-erase suspend sector address will indicate logic “1” at the DQ<sub>2</sub> bit.

\*3 : DQ<sub>1</sub> indicates the Write-to-Buffer ABORT status during Write-Buffer-Programming operations.

\*4 : The  $\overline{Data}$  Polling algorithm detailed in “ $\overline{Data}$  Polling Algorithm” in ■FLOW CHART should be used for Write-Buffer-Programming operations. Note that  $\overline{DQ}_7$  during Write-Buffer-Programming indicates the data-bar for DQ<sub>7</sub> data for the LAST LOADED WRITE-BUFFER ADDRESS location.

**DQ<sub>7</sub>****Data Polling**

The devices feature  $\overline{\text{Data}}$  Polling as a method to indicate to the host that the Embedded Algorithms are in progress or completed. During the Embedded Program Algorithm, an attempt to read devices will produce reverse data last written to DQ<sub>7</sub>. Upon completion of the Embedded Program Algorithm, an attempt to read the device will produce true data last written to DQ<sub>7</sub>. For programming, the  $\overline{\text{Data}}$  Polling is valid after the rising edge of fourth write pulse in the four write pulse sequence. During the Embedded Erase Algorithm, an attempt to read the device will produce a “0” at the DQ<sub>7</sub> output. Upon completion of the Embedded Erase Algorithm, an attempt to read device will produce a “1” at the DQ<sub>7</sub> output. The flowchart for  $\overline{\text{Data}}$  Polling (DQ<sub>7</sub>) is shown in “Data Polling Algorithm” in ■FLOW CHART.

For chip erase and sector erase, the  $\overline{\text{Data}}$  Polling is valid after the rising edge of the sixth write pulse in the six write cycles.  $\overline{\text{Data}}$  Polling must be performed at sector addresses of sectors being erased, not protected sectors. Otherwise, the status may become invalid.

If a program address falls within a protected sector, Data polling on DQ<sub>7</sub> is active for approximately 1  $\mu\text{s}$ , then the device returns to read mode. After an erase command sequence is written, if all sectors selected for erasing are protected,  $\overline{\text{Data}}$  Polling on DQ<sub>7</sub> is active for approximately 400  $\mu\text{s}$ , then the device returns to read mode. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected.

Once the Embedded Algorithm operation is close to being completed, the device data pins (DQ<sub>7</sub>) may change asynchronously while the output enable ( $\overline{\text{OE}}$ ) is asserted low. This means that the device is driving status information on DQ<sub>7</sub> at one instant of time, and then that byte's valid data the next. Depending on when the system samples the DQ<sub>7</sub> output, it may read the sequence flag or valid data. Even if the device completes the Embedded Algorithm operation and DQ<sub>7</sub> has a valid data, the data outputs on DQ<sub>6</sub> to DQ<sub>0</sub> may still be invalid. The valid data on DQ<sub>7</sub> to DQ<sub>0</sub> will be read on the successive read attempts.

The  $\overline{\text{Data}}$  Polling feature is active only during the Embedded Programming Algorithm, Embedded Erase Algorithm, Erase Suspend mode or sector erase time-out.

See “ $\overline{\text{Data}}$  Polling during Embedded Algorithm Operation Timing Diagram” in ■TIMING DIAGRAM for the  $\overline{\text{Data}}$  Polling timing specifications and diagram.

**DQ<sub>6</sub>****Toggle Bit I**

The device also feature the “Toggle Bit I” as a method to indicate to the host system that the Embedded Algorithms are in progress or completed.

During an Embedded Program or Erase Algorithm cycle, successive attempts to read ( $\overline{\text{CE}}$  or  $\overline{\text{OE}}$  toggling) data from the devices will result in DQ<sub>6</sub> toggling between 1 and 0. Once the Embedded Program or Erase Algorithm cycle is completed, DQ<sub>6</sub> will stop toggling and valid data will be read on the next successive attempts. During programming, the Toggle Bit I is valid after the rising edge of the fourth write pulse in the four write cycles. For chip erase and sector erase, the Toggle Bit I is valid after the rising edge of the sixth write pulse in the six write cycles. The Toggle Bit I is active during the sector time out.

In programm operation, if the sector being written to is protected, the Toggle bit will toggle for about 1  $\mu\text{s}$  and then stop toggling with the data unchanged. In erase, the device will erase all the selected sectors except for the protected ones. If all selected sectors are protected, the chip will toggle the Toggle bit for about 400  $\mu\text{s}$  and then drop back into read mode, having data kept remained.

Either  $\overline{\text{CE}}$  or  $\overline{\text{OE}}$  toggling will cause the DQ<sub>6</sub> to toggle. See “Toggle Bit I Timing Diagram during Embedded Algorithm Operations” in ■TIMING DIAGRAM for the Toggle Bit I timing specifications and diagram.

## DQ<sub>5</sub>

### Exceeded Timing Limits

DQ<sub>5</sub> will indicate if the program or erase time has exceeded the specified limits (internal pulse count). Under these conditions DQ<sub>5</sub> will produce a “1”. This is a failure condition indicating that the program or erase cycle was not successfully completed.  $\overline{\text{Data}}$  Polling is the only operating function of the device under this condition. The  $\overline{\text{CE}}$  circuit will partially power down the device under these conditions (to approximately 2 mA). The  $\overline{\text{OE}}$  and  $\overline{\text{WE}}$  pins will control the output disable functions as described in “MBM29PL12LM User Bus Operations (Word Mode :  $\overline{\text{BYTE}} = V_{\text{IH}}$ )” and “MBM29PL12LM User Bus Operations (Byte Mode :  $\overline{\text{BYTE}} = V_{\text{IL}}$ )” in ■DEVICE BUS OPERATION.

The DQ<sub>5</sub> failure condition may also appear if a user tries to program a non blank location without pre-erase. In this case the device locks out and never completes the Embedded Algorithm operation. Hence, the system never reads a valid data on DQ<sub>7</sub> bit and DQ<sub>6</sub> never stop toggling. Once the device has exceeded timing limits, the DQ<sub>5</sub> bit will indicate a “1”. Note that this is not a device failure condition since the device was incorrectly used. If this occurs, reset the device with command sequence.

## DQ<sub>3</sub>

### Sector Erase Timer

After the completion of the initial sector erase command sequence the sector erase time-out will begin. DQ<sub>3</sub> will remain low until the time-out is complete.  $\overline{\text{Data}}$  Polling and Toggle Bit are valid after the initial sector erase command sequence.

If  $\overline{\text{Data}}$  Polling or the Toggle Bit I indicates a valid erase command has been written, DQ<sub>3</sub> may be used to determine whether the sector erase timer window is still open. If DQ<sub>3</sub> is “1” the internally controlled erase cycle has begun. If DQ<sub>3</sub> is “0”, the device will accept additional sector erase commands. To insure the command has been accepted, the system software should check the status of DQ<sub>3</sub> prior to and following each subsequent Sector Erase command. If DQ<sub>3</sub> were high on the second status check, the command may not have been accepted.

See “Hardware Sequence Flags”.

## DQ<sub>2</sub>

### Toggle Bit II

This Toggle bit II, along with DQ<sub>6</sub>, can be used to determine whether the devices are in the Embedded Erase Algorithm or in Erase Suspend.

Successive reads from the erasing sector will cause DQ<sub>2</sub> to toggle during the Embedded Erase Algorithm. If the devices are in the erase-suspended-read mode, successive reads from the erase-suspended sector will cause DQ<sub>2</sub> to toggle. When the device is in the erase-suspended-program mode, successive reads from the non-erase suspended sector will indicate a logic “1” at the DQ<sub>2</sub> bit.

DQ<sub>6</sub> is different from DQ<sub>2</sub> in that DQ<sub>6</sub> toggles only when the standard program or Erase, or Erase Suspend Program operation is in progress. The behavior of these two status bits, along with that of DQ<sub>7</sub>, is summarized as follows:

For example, DQ<sub>2</sub> and DQ<sub>6</sub> can be used together to determine if the erase-suspend-read mode is in progress. (DQ<sub>2</sub> toggles while DQ<sub>6</sub> does not.) See also “Hardware Sequence Flags” and “DQ<sub>2</sub> vs. DQ<sub>6</sub>” in ■TIMING DIAGRAM.

Furthermore, DQ<sub>2</sub> can also be used to determine which sector is being erased. At the erase mode, DQ<sub>2</sub> toggles if this bit is read from an erasing sector.

## Reading Toggle Bits DQ<sub>6</sub> / DQ<sub>2</sub>

Whenever the system initially begins reading Toggle bit status, it must read DQ<sub>7</sub> to DQ<sub>0</sub> at least twice in a row to determine whether a Toggle bit is toggling. Typically a system would note and store the value of the Toggle bit after the first read. After the second read, the system would compare the new value of the Toggle bit with the first. If the Toggle bit is not toggling, the device has completed the program or erase operation. The system can read array data on DQ<sub>7</sub> to DQ<sub>0</sub> on the following read cycle.

However, if, after the initial two read cycles, the system determines that the Toggle bit is still toggling, the system also should note whether the value of DQ<sub>5</sub> is high (see the section on DQ<sub>5</sub>) . If it is, the system should then determine again whether the Toggle bit is toggling, since the Toggle bit may have stopped toggling just as DQ<sub>5</sub> went high. If the Toggle bit is no longer toggling, the device has successfully completed the program or erase operation. If it is still toggling, the device did not complete the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the Toggle bit is toggling and DQ<sub>5</sub> has not gone high. The system may continue to monitor the Toggle bit and DQ<sub>5</sub> through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation. (Refer to “Toggle Bit Algorithm” in ■FLOW CHART.)

**Toggle Bit Status**

Mode	DQ <sub>7</sub>	DQ <sub>6</sub>	DQ <sub>2</sub>
Program	$\overline{DQ}_7$	Toggle	1
Erase	0	Toggle	Toggle *1
Erase-Suspend-Read (Erase-Suspended Sector)	1	1	Toggle *1
Erase-Suspend-Program	$\overline{DQ}_7$	Toggle	1 *2

\*1 : Successive reads from the erasing or erase-suspend sector will cause DQ<sub>2</sub> to toggle.

\*2 : Reading from the non-erase suspend sector address will indicate logic “1” at the DQ<sub>2</sub> bit.

## DQ<sub>1</sub>

### Write-to-Buffer Abort

DQ<sub>1</sub> indicates whether a Write-to-Buffer operation was aborted. Under these conditions DQ<sub>1</sub> produces a “1”. The system must issue the Write-to-Buffer-Abort-Reset command sequence to return the device to reading array data. See “Write Buffer Programming Operations” section for more details.

## $\overline{RY/BY}$

### Ready/Busy

The device provides a  $\overline{RY/BY}$  open-drain output pin to indicate to the host system that the Embedded Algorithms are either in progress or has been completed. If the output is low, the device is busy with either a program or erase operation. If the output is high impedance, the device is ready to accept any write or erase operation. If the device is placed in an Erase Suspend mode, the  $\overline{RY/BY}$  output will be high, by means of connecting with a pull-up resistor.

During programming, the  $\overline{RY/BY}$  pin is driven low after the rising edge of the fourth  $\overline{WE}$  pulse. During an erase operation, the  $\overline{RY/BY}$  pin is driven low after the rising edge of the sixth  $\overline{WE}$  pulse. The  $\overline{RY/BY}$  pin will indicate a ready condition during the  $\overline{RESET}$  is  $V_{IL}$ . See “ $\overline{RY/BY}$  Timing Diagram during Program/Erase Operation Timing Diagram” and “ $\overline{RESET}$  Timing Diagram ( During Embedded Algorithms )” in “■TIMING DIAGRAM” for a detailed timing diagram. The  $\overline{RY/BY}$  pin is pulled high in standby mode.

Since this is an open-drain output,  $\overline{RY/BY}$  pins can be tied together in parallel with a pull-up resistor to  $V_{CC}$ .

## Word/Byte Configuration

$\overline{\text{BYTE}}$  pin selects the byte (8-bit) mode or word (16-bit) mode for the device. When this pin is driven high, the device operates in the word (16-bit) mode. Data is read and programmed at DQ<sub>15</sub> to DQ<sub>0</sub>. When this pin is driven low, the device operates in byte (8-bit) mode. In this mode, DQ<sub>15</sub>/A<sub>-1</sub> pin becomes the lowest address bit, and DQ<sub>14</sub> to DQ<sub>8</sub> bits are High-Z. However, the command bus cycle is always an 8-bit operation and hence commands are written at DQ<sub>7</sub> to DQ<sub>0</sub> and DQ<sub>15</sub> to DQ<sub>8</sub> bits are ignored.

## Data Protection

The device is designed to offer protection against accidental erasure or programming caused by spurious system level signals that may exist during power transitions. During power up the device automatically reset the internal state machine in Read mode. Also, with its command register architecture, alteration of memory contents only occurs after successful completion of specific multi-bus cycle command sequences.

The device also incorporates several features to prevent inadvertent write cycles resulting from V<sub>CC</sub> power-up and power-down transitions or system noise.

### (1) Low V<sub>CC</sub> Write Inhibit

To avoid initiation of a write cycle during V<sub>CC</sub> power-up and power-down, a write cycle is locked out for V<sub>CC</sub> less than V<sub>LKO</sub>. If V<sub>CC</sub> < V<sub>LKO</sub>, the command register is disabled and all internal program/erase circuits are disabled. Under this condition, the device will reset to the read mode. Subsequent writes will be ignored until the V<sub>CC</sub> level is greater than V<sub>LKO</sub>. It is the user's responsibility to ensure that the control pins are logically correct to prevent unintentional writes when V<sub>CC</sub> is above V<sub>LKO</sub>.

If Embedded Erase Algorithm is interrupted, the intervened erasing sector(s) is(are) not valid.

### (2) Write Pulse "Glitch" Protection

Noise pulses of less than 3 μs (typical) on  $\overline{\text{OE}}$ ,  $\overline{\text{CE}}$ , or  $\overline{\text{WE}}$  will not initiate a write cycle.

### (3) Logical Inhibit

Writing is inhibited by holding any one of  $\overline{\text{OE}} = V_{\text{IL}}$ ,  $\overline{\text{CE}} = V_{\text{IH}}$ , or  $\overline{\text{WE}} = V_{\text{IH}}$ . To initiate a write,  $\overline{\text{CE}}$  and  $\overline{\text{WE}}$  must be low while  $\overline{\text{OE}}$  is high.

### (4) Power-up Write Inhibit

Power-up of the devices with  $\overline{\text{WE}} = \overline{\text{CE}} = V_{\text{IL}}$  and  $\overline{\text{OE}} = V_{\text{IH}}$  will not accept commands on the rising edge of  $\overline{\text{WE}}$ . The internal state machine is automatically set to read mode on power-up.

### (5) Sector Protection

Device is able to protect each sector group to store and protect data in the user side. Protection circuit voids both write and erase commands that are addressed to protected sectors.

Any commands to write or erase addressed to protected sector are ignored.

See "Sector Group Protection" in ■FUNCTIONAL DESCRIPTION.

## ■ ABSOLUTE MAXIMUM RATINGS

Parameter	Symbol	Rating		Unit
		Min	Max	
Storage Temperature	T <sub>stg</sub>	-55	+125	°C
Ambient Temperature with Power Applied	T <sub>A</sub>	-20	+85	°C
Voltage with Respect to Ground All Pins Except A <sub>9</sub> , $\overline{OE}$ , and $\overline{RESET}$ *1,*2	V <sub>IN</sub> , V <sub>OUT</sub>	-0.5	V <sub>CC</sub> +0.5	V
Power Supply Voltage *1	V <sub>CC</sub>	-0.5	+4.0	V
A <sub>9</sub> , $\overline{OE}$ , and $\overline{RESET}$ *1,*3	V <sub>IN</sub>	-0.5	+12.5	V
$\overline{WP/ACC}$ *1,*3	V <sub>ACC</sub>	-0.5	+12.5	V

\*1 : Voltage is defined on the basis of V<sub>SS</sub> = GND = 0 V.

\*2 : Minimum DC voltage on input or I/O pins is -0.5 V. During voltage transitions, input or I/O pins may undershoot V<sub>SS</sub> to -0.2 V for periods of up to 20 ns. Maximum DC voltage on input or I/O pins is V<sub>CC</sub> +0.5 V. During voltage transitions, input or I/O pins may overshoot to V<sub>CC</sub> +2.0 V for periods of up to 20 ns

\*3 : Minimum DC input voltage is -0.5V. During voltage transitions, these pins may undershoot V<sub>SS</sub> to -0.2 V for periods of up to 20 ns. Voltage difference between input and supply voltage ( V<sub>IN</sub>-V<sub>CC</sub>) dose not exceed to +9.0 V. Maximum DC input voltage is +12.5 V which may overshoot to +14.0 V for periods of up to 20 ns .

WARNING: Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

## ■ RECOMMENDED OPERATING RANGES\*1

Parameter	Symbol	Value		Unit
		Min	Max	
Ambient Temperature	T <sub>A</sub>	-20	+85	°C
V <sub>CC</sub> Supply Voltage *2, *3	V <sub>CC</sub>	+3.0	+3.6	V
V <sub>CCQ</sub> Supply Voltage *2, *3	V <sub>CCQ</sub>	V <sub>CC</sub>		V

\*1 : Operating ranges define those limits between which the functionality of the device is guaranteed.

\*2 : Voltage is defined on the basis of V<sub>SS</sub> = GND = 0V.

\*3 : See if V<sub>CC</sub> and V<sub>CCQ</sub> are of the same value.

WARNING: The recommended operating conditions are required in order to ensure the normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.

Always use semiconductor devices within their recommended operating condition ranges. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their FUJITSU representatives beforehand.

## ■ MAXIMUM OVERSHOOT/MAXIMUM UNDERSHOOT

Maximum Undershoot Waveform

Maximum Overshoot Waveform 1

Note: This waveform is applied for  $A_9$ ,  $\overline{OE}$ ,  $\overline{RESET}$ , and  $\overline{WP/ACC}$ .

Maximum Overshoot Waveform 2

## ■ ELECTRICAL CHARACTERISTICS

### 1. DC Characteristics

Parameter	Symbol	Conditions	Value			Unit	
			Min	Typ	Max		
Input Leakage Current	I <sub>LI</sub>	V <sub>IN</sub> = V <sub>SS</sub> to V <sub>CC</sub> , V <sub>CC</sub> = V <sub>CC</sub> Max	$\overline{WP}/ACC$ pin	-2.0	—	+2.0	μA
			Others	-1.0	—	+1.0	
Output Leakage Current	I <sub>LO</sub>	V <sub>OUT</sub> = V <sub>SS</sub> to V <sub>CC</sub> , V <sub>CC</sub> = V <sub>CC</sub> Max	-1.0	—	+1.0	μA	
A <sub>9</sub> , $\overline{OE}$ , $\overline{RESET}$ Inputs Leakage Current	I <sub>LIT</sub>	V <sub>CC</sub> = V <sub>CC</sub> Max, A <sub>9</sub> , $\overline{OE}$ , $\overline{RESET}$ = 12.5 V	—	—	35	μA	
V <sub>CC</sub> Active Current (Read) *1,*2	I <sub>CC1</sub>	$\overline{CE}$ = V <sub>IL</sub> , $\overline{OE}$ = V <sub>IH</sub> , f = 5 MHz	Word	—	15	25	mA
			Byte	—	15	25	
		$\overline{CE}$ = V <sub>IL</sub> , $\overline{OE}$ = V <sub>IH</sub> , f = 10 MHz	Word	—	35	50	
			Byte	—	35	50	
V <sub>CC</sub> Active Current (Intra-Page Read) *2	I <sub>CC2</sub>	$\overline{CE}$ = V <sub>IL</sub> , $\overline{OE}$ = V <sub>IH</sub> , t <sub>PRC</sub> = 25ns, 4-Word	—	10	20	mA	
V <sub>CC</sub> Active Current (Program / Erase) *2,*3	I <sub>CC3</sub>	$\overline{CE}$ = V <sub>IL</sub> , $\overline{OE}$ = V <sub>IH</sub>	—	50	60	mA	
V <sub>CC</sub> Standby Current *2	I <sub>CC4</sub>	$\overline{CE}$ = V <sub>CC</sub> ± 0.3 V, $\overline{RESET}$ = V <sub>CC</sub> ± 0.3 V, $\overline{OE}$ = V <sub>IH</sub> , $\overline{WP}/ACC$ = V <sub>CC</sub> ± 0.3 V	—	1	5	μA	
V <sub>CC</sub> Reset Current *2	I <sub>CC5</sub>	$\overline{RESET}$ = V <sub>CC</sub> ± 0.3 V, $\overline{WP}/ACC$ = V <sub>CC</sub> ± 0.3 V	—	1	5	μA	
V <sub>CC</sub> Automatic Sleep Current *4	I <sub>CC6</sub>	$\overline{CE}$ = V <sub>SS</sub> ± 0.3 V, $\overline{RESET}$ = V <sub>CC</sub> ± 0.3 V, V <sub>IN</sub> = V <sub>CC</sub> ± 0.3V or V <sub>SS</sub> ± 0.3V, $\overline{WP}/ACC$ = V <sub>CC</sub> ± 0.3 V	—	1	5	μA	
V <sub>CC</sub> Active Current (Erase-Suspend-Program) *2	I <sub>CC7</sub>	$\overline{CE}$ = V <sub>IL</sub> , $\overline{OE}$ = V <sub>IH</sub>	—	50	60	mA	
ACC Accelerated Program Current	I <sub>ACC</sub>	$\overline{CE}$ = V <sub>IL</sub> , $\overline{OE}$ = V <sub>IH</sub> , V <sub>CC</sub> = V <sub>CC</sub> Max, $\overline{WP}/ACC$ = V <sub>ACC</sub> Max	$\overline{WP}/ACC$ pin	—	—	45	mA
			V <sub>CC</sub> Pin	—	—	60	
Input Low Level	V <sub>IL</sub>	—	-0.5	—	0.6	V	
Input High Level	V <sub>IH</sub>	—	0.7×V <sub>CC</sub>	—	V <sub>CC</sub> + 0.3	V	
Voltage for $\overline{WP}/ACC$ Sector Protection/Unprotection and Program Acceleration	V <sub>ACC</sub>	V <sub>CC</sub> = 3.0 V to 3.6 V	11.5	12.0	12.5	V	
Voltage for Autoselect, and Temporary Sector Unprotected	V <sub>ID</sub>	V <sub>CC</sub> = 3.0 V to 3.6 V	11.5	12.0	12.5	V	
Output Low Voltage Level	V <sub>OL</sub>	I <sub>OL</sub> = 4.0 mA, V <sub>CC</sub> = V <sub>CC</sub> Min	—	—	0.45	V	
Output High Voltage Level	V <sub>OH</sub>	I <sub>OH</sub> = -2.0 mA, V <sub>CC</sub> = V <sub>CC</sub> Min	0.85×V <sub>CCQ</sub>	—	—	V	
Low V <sub>CC</sub> Lock-Out Voltage	V <sub>LKO</sub>	—	2.3	—	2.5	V	

# MBM29PL12LM<sub>10</sub>

- \*1 : The  $I_{CC}$  current listed includes both the DC operating current and the frequency dependent component.
- \*2 :  $I_{CC}$  peaks when both  $V_{CC}$  and  $V_{CCQ}$  are at their Max.
- \*3 :  $I_{CC}$  active while Embedded Erase or Embedded Program or Write Buffer Programming is in progress.
- \*4 : Automatic sleep mode enables the low power mode when address remain stable for  $t_{ACC} + 30$  ns.

## 2. AC Characteristics

### • Read Only Operations Characteristics

Parameter	Symbols		Condition	Value*		Unit
	JEDEC	Standard		10		
				Min	Max	
Read Cycle Time	t <sub>AVAV</sub>	t <sub>RC</sub>	—	100	—	ns
Address to Output Delay	t <sub>AVQV</sub>	t <sub>ACC</sub>	$\overline{CE} = V_{IL},$ $\overline{OE} = V_{IL}$	—	100	ns
Chip Enable to Output Delay	t <sub>ELQV</sub>	t <sub>CE</sub>	$\overline{OE} = V_{IL}$	—	100	ns
Page Read Cycle Time	—	t <sub>PRC</sub>	—	25	—	ns
Page Address to Output Delay	—	t <sub>PACC</sub>	$\overline{CE} = V_{IL},$ $\overline{OE} = V_{IL}$	—	30	ns
Output Enable to Output Delay	t <sub>GLQV</sub>	t <sub>OE</sub>	—	—	30	ns
Chip Enable to Output High-Z	t <sub>EHQZ</sub>	t <sub>DF</sub>	—	—	25	ns

## ■ ERASE AND PROGRAMMING PERFORMANCE

Parameter	Limits			Unit	Remarks
	Min	Typ	Max		
Sector Erase Time	—	1	15	s	Excludes programming time prior to erasure
Programming Time	—	100	3000	μs	Excludes system-level overhead
Effective Page Programming Time (Write Buffer Programming)	—	23.5	—	μs	
Chip Programming Time	—	—	1200	s	
Absolute Maximum Programming Time (16 words)	—	—	6	ms	Non programming within the same page
Erase/Program Cycle	100,000	—	—	cycle	—

## ■ TSOP (1) PIN CAPACITANCE

Parameter	Symbol	Test Setup	Value		Unit
			Typ	Max	
Input Capacitance	C <sub>IN</sub>	V <sub>IN</sub> = 0	8	10	pF
Output Capacitance	C <sub>OUT</sub>	V <sub>OUT</sub> = 0	8.5	12	pF
Control Pin Capacitance	C <sub>IN2</sub>	V <sub>IN</sub> = 0	8	10	pF
Reset pin and $\overline{WP}/ACC$ Pin Capacitance	C <sub>IN3</sub>	V <sub>IN</sub> = 0	20	25	pF

Notes : • Test conditions T<sub>A</sub> = +25°C, f = 1.0 MHz  
 • DQ<sub>15</sub>/A-1 pin capacitance is stipulated by output capacitance.

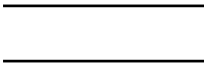

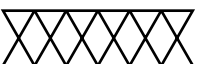

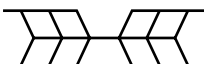

## ■ FBGA PIN CAPACITANCE

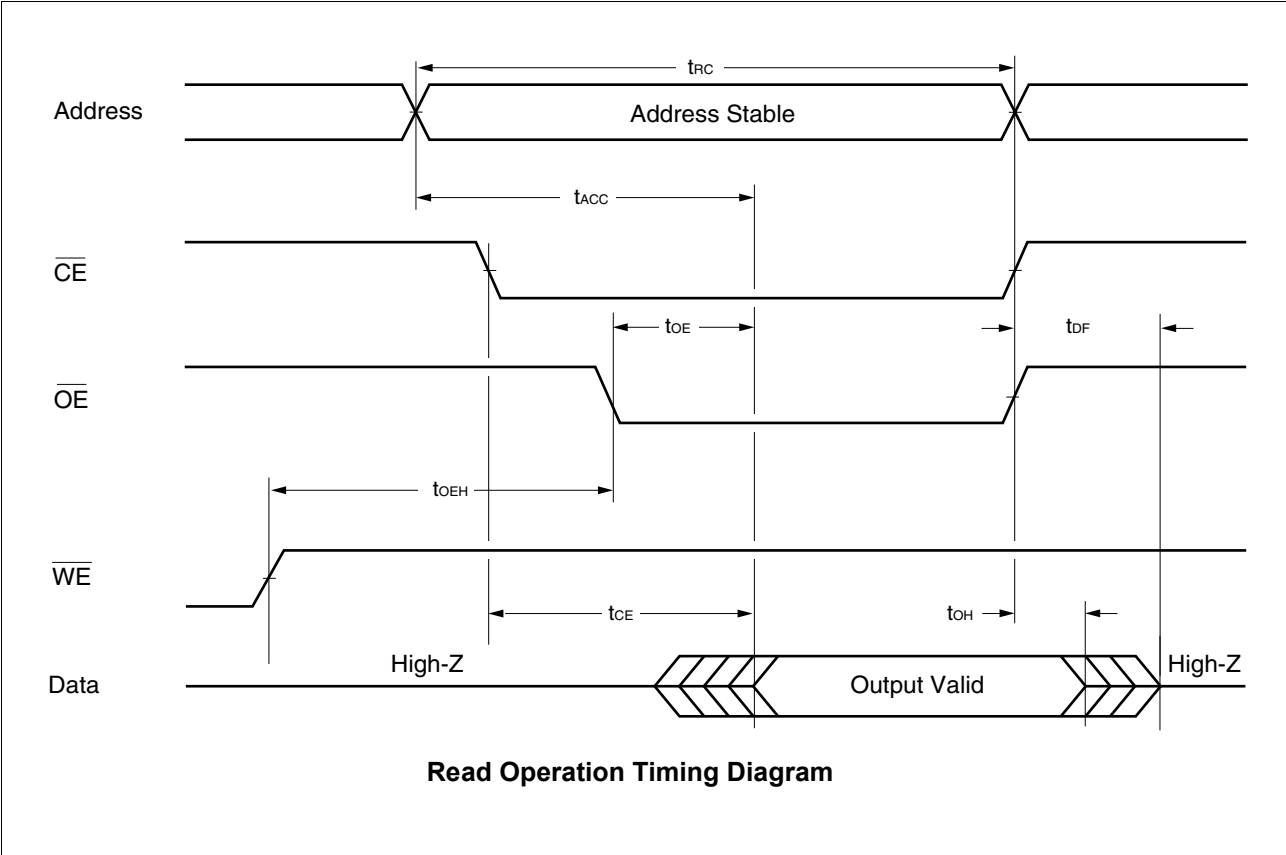

Parameter	Symbol	Test Setup	Value		Unit
			Typ	Max	
Input Capacitance	C <sub>IN</sub>	V <sub>IN</sub> = 0	8	10	pF
Output Capacitance	C <sub>OUT</sub>	V <sub>OUT</sub> = 0	8.5	12	pF
Control Pin Capacitance	C <sub>IN2</sub>	V <sub>IN</sub> = 0	8	10	pF
Reset pin and $\overline{WP}/ACC$ Pin Capacitance	C <sub>IN3</sub>	V <sub>IN</sub> = 0	15	20	pF

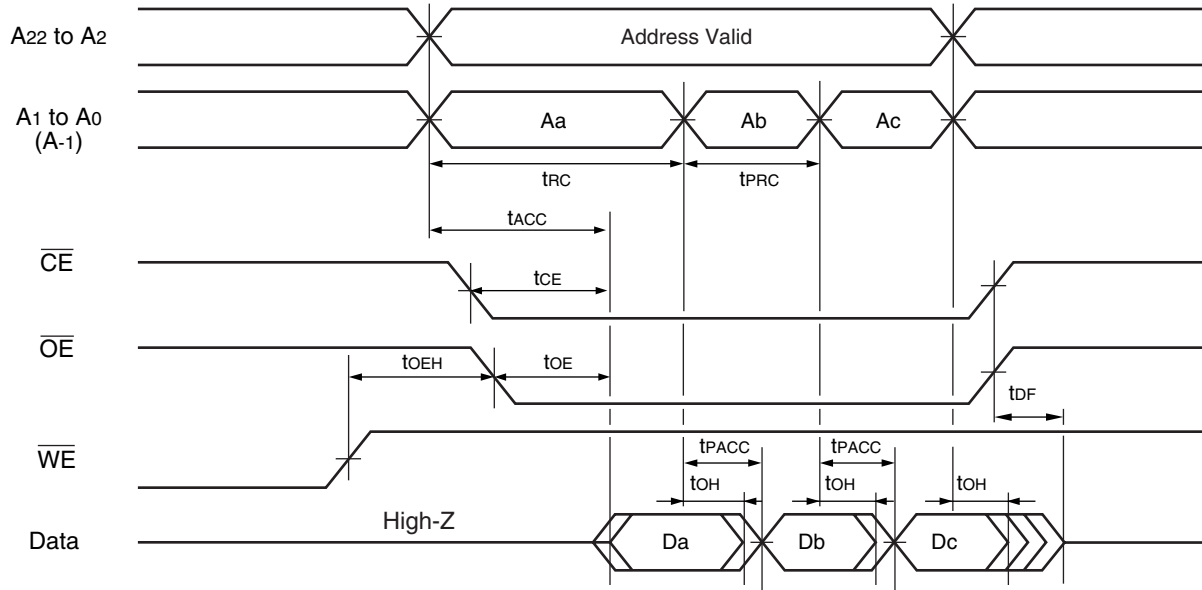

Notes : • Test conditions T<sub>A</sub> = +25°C, f = 1.0 MHz  
 • DQ<sub>15</sub>/A-1 pin capacitance is stipulated by output capacitance.

## TIMING DIAGRAM

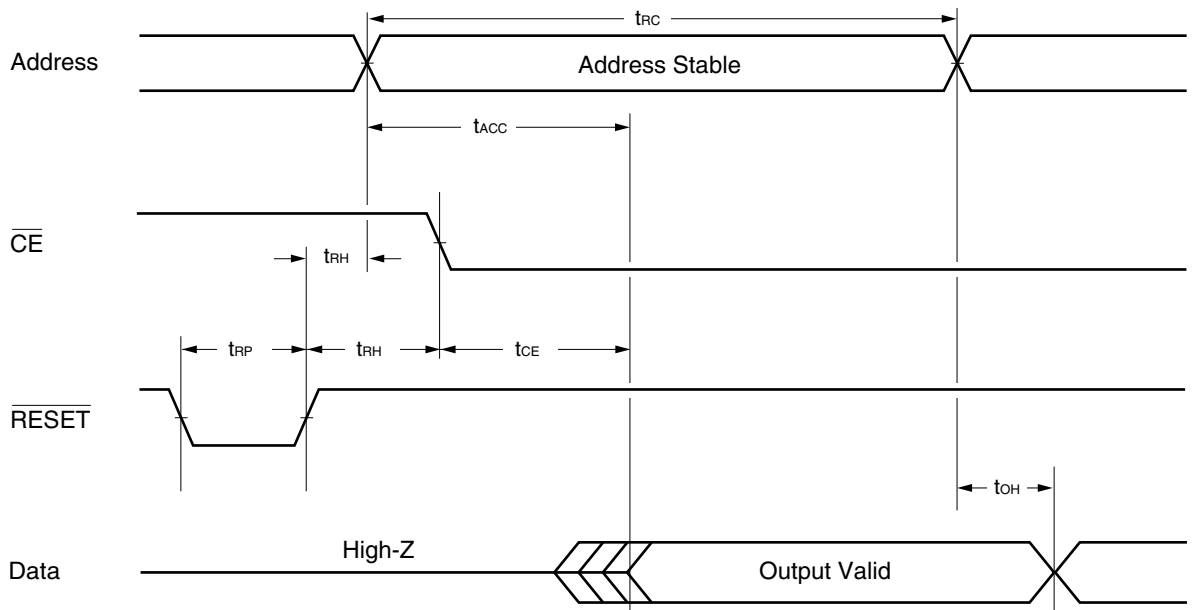

### Key to Switching Waveforms

WAVEFORM	INPUTS	OUTPUTS
	Must Be Steady	Will Be Steady
	May Change from H to L	Will Be Changing from H to L
	May Change from L to H	Will Be Changing from L to H
	"H" or "L" Any Change Permitted	Changing State Unknown
	Does Not Apply	Center Line is High-Impedance "Off" State

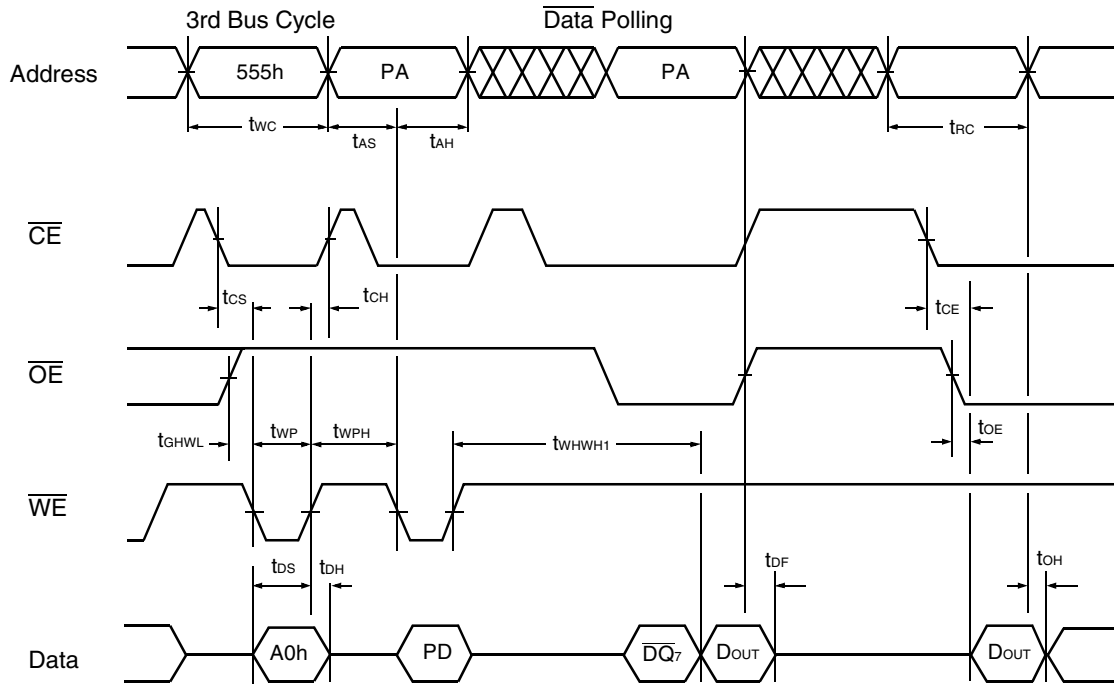

**Page Read Operation Timing Diagram**

**Hardware Reset/Read Operation Timing Diagram**

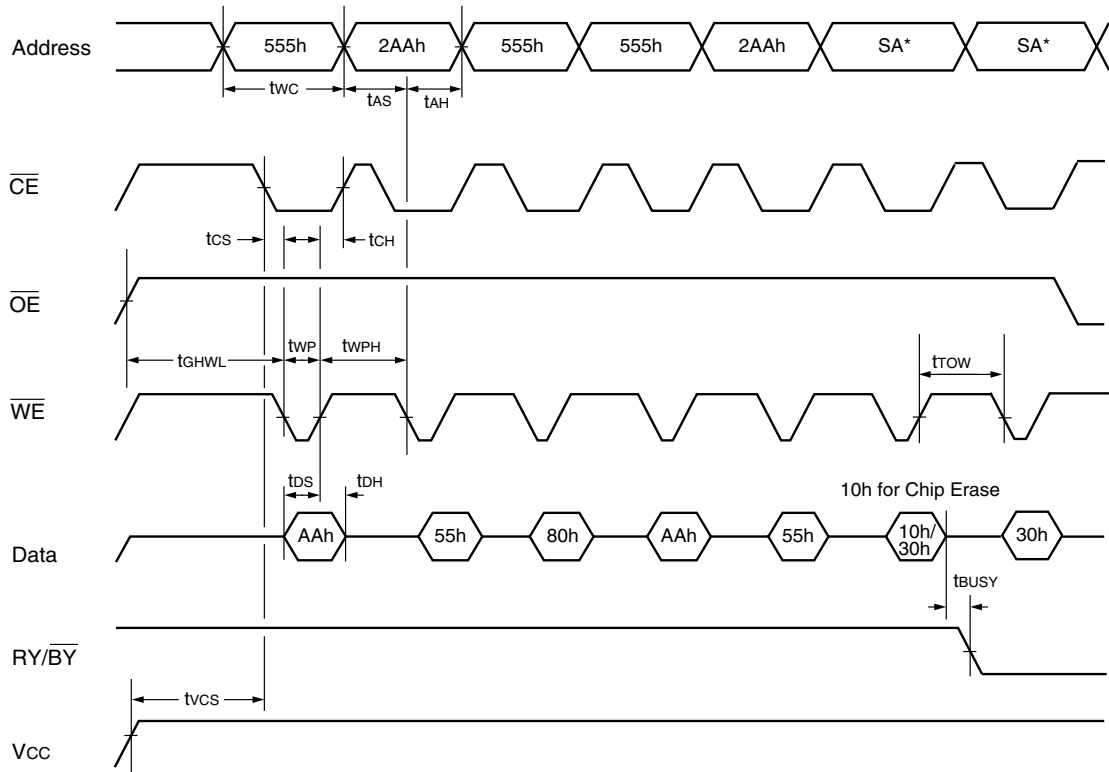

- Notes :
- PA is address of the memory location to be programmed.
  - PD is data to be programmed at word address.
  - $\overline{DQ}_7$  is the output of the complement of the data written to the device.
  - $D_{OUT}$  is the output of the data written to the device.
  - Figure indicates the last two bus cycles out of four bus cycle sequence.

**Alternate  $\overline{WE}$  Controlled Program Operation Timing Diagram**

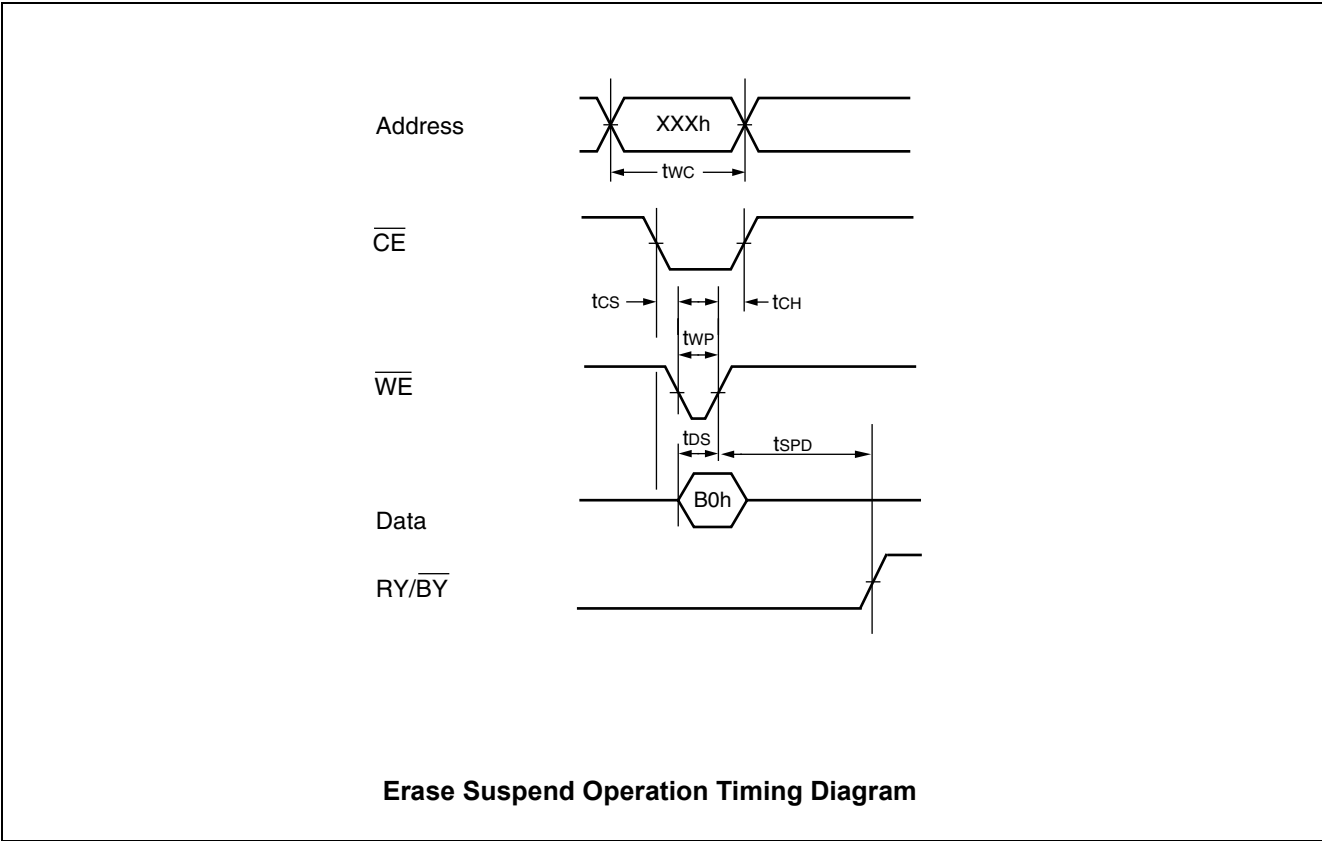

- Notes :
- PA is address of the memory location to be programmed.
  - PD is data to be programmed at word address.
  - $\overline{DQ}_7$  is the output of the complement of the data written to the device.
  - $D_{OUT}$  is the output of the data written to the device.
  - Figure indicates the last two bus cycles out of four bus cycle sequence.

Alternate  $\overline{CE}$  Controlled Program Operation Timing Diagram

\* : SA is the sector address for Sector Erase. Address = 555h (Word), AAh (Byte) for Chip Erase.

**Chip/Sector Erase Operation Timing Diagram**

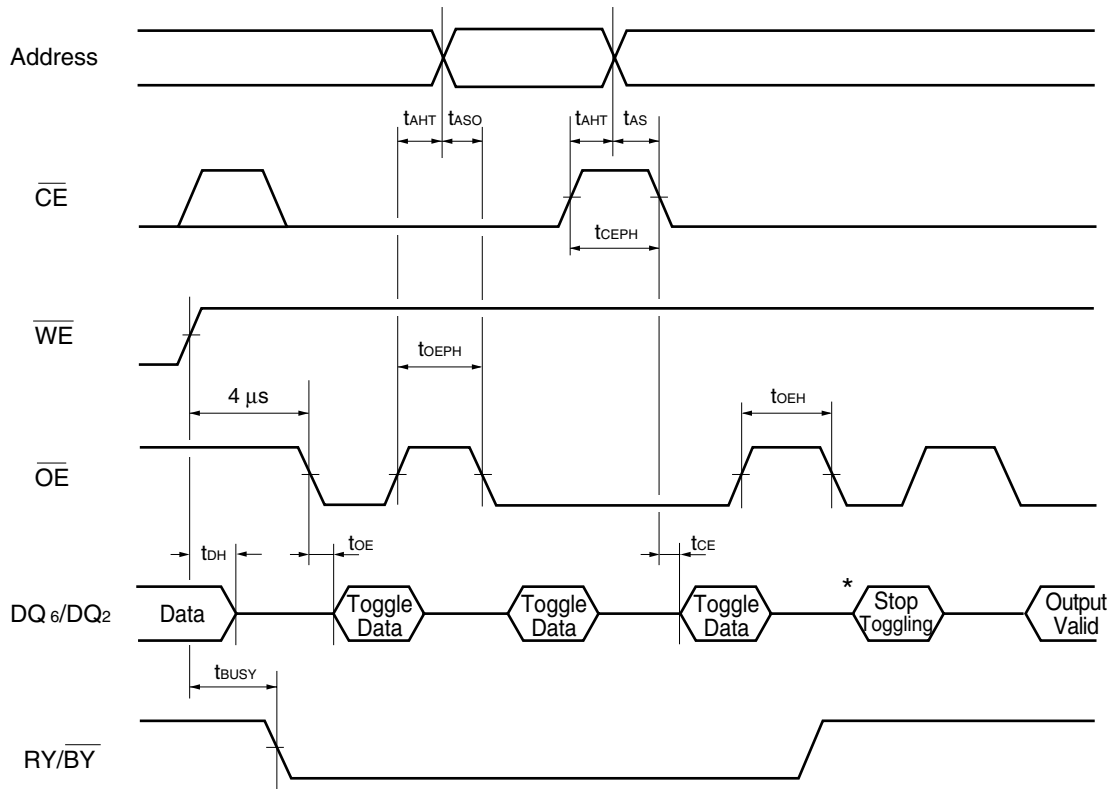

\* : DQ<sub>7</sub> = Valid Data (The device has completed the Embedded operation.)

Note : When checking Hardware Sequence Flags during program operations, it should be checked 4  $\mu s$  after issuing program command.

**Data Polling during Embedded Algorithm Operation Timing Diagram**

\* :  $DQ_6$  stops toggling (The device has completed the Embedded operation).

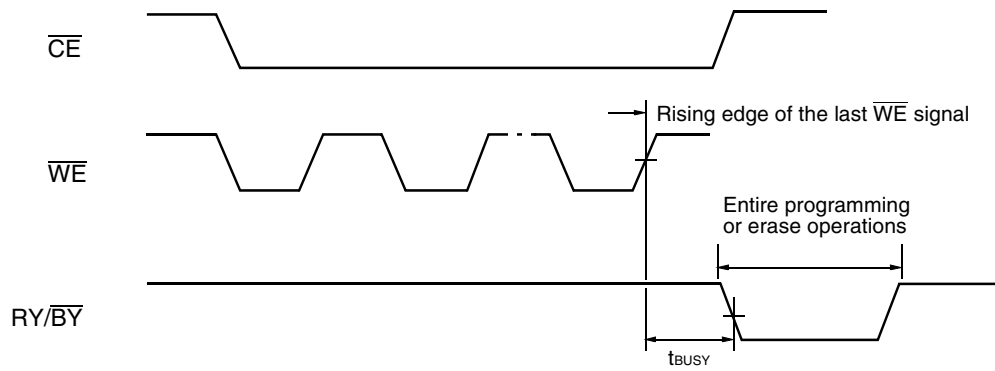

Note : When checking Hardware Sequence Flags during program operations, it should be checked 4  $\mu s$  after issuing program command.

**Toggle Bit Timing Diagram during Embedded Algorithm Operations**

\* :  $DQ_2$  is read from the erase-suspended sector.

**$DQ_2$  vs.  $DQ_6$**

■ FLOW CHART

EMBEDDED ALGORITHMS

Program Command Sequence (Address/Command):

Note : The sequence is applied for Word ( ×16 ) mode.  
The addresses differ from Byte ( × 8 ) mode.

**Embedded Program™ Algorithm**

## EMBEDDED ALGORITHMS

Chip Erase Command Sequence  
(Address/Command):

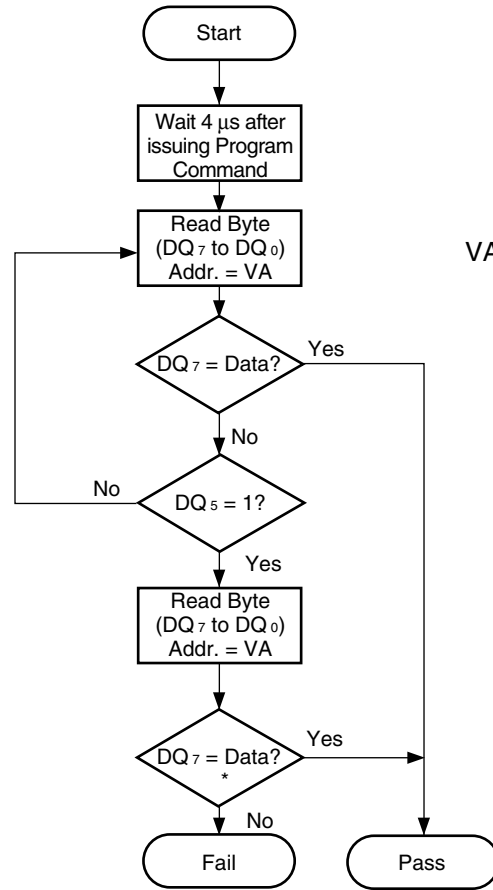

Individual Sector/Multiple Sector  
Erase Command Sequence  
(Address/Command):

Note : The sequence is applied for Word ( × 16 ) mode.  
The addresses differ from Byte ( × 8 ) mode.

### Embedded Erase™ Algorithm

VA = Valid address for programming  
 = Any of the sector addresses within the sector being erased during sector erase or multiple sector erases operation  
 = Any of the sector addresses within the sector not being protected during chip erase operation

\* : DQ<sub>7</sub> is rechecked even if DQ<sub>5</sub> = "1" because DQ<sub>7</sub> may change simultaneously with DQ<sub>5</sub>.

### Data Polling Algorithm

\*1 : Read Toggle bit twice to determine whether it is toggling.

\*2 : Recheck Toggle bit because it may stop toggling as DQ<sub>5</sub> changes to "1".

### Toggle Bit Algorithm

\* : A-1 is V<sub>IL</sub> in Byte ( × 8 ) mode.

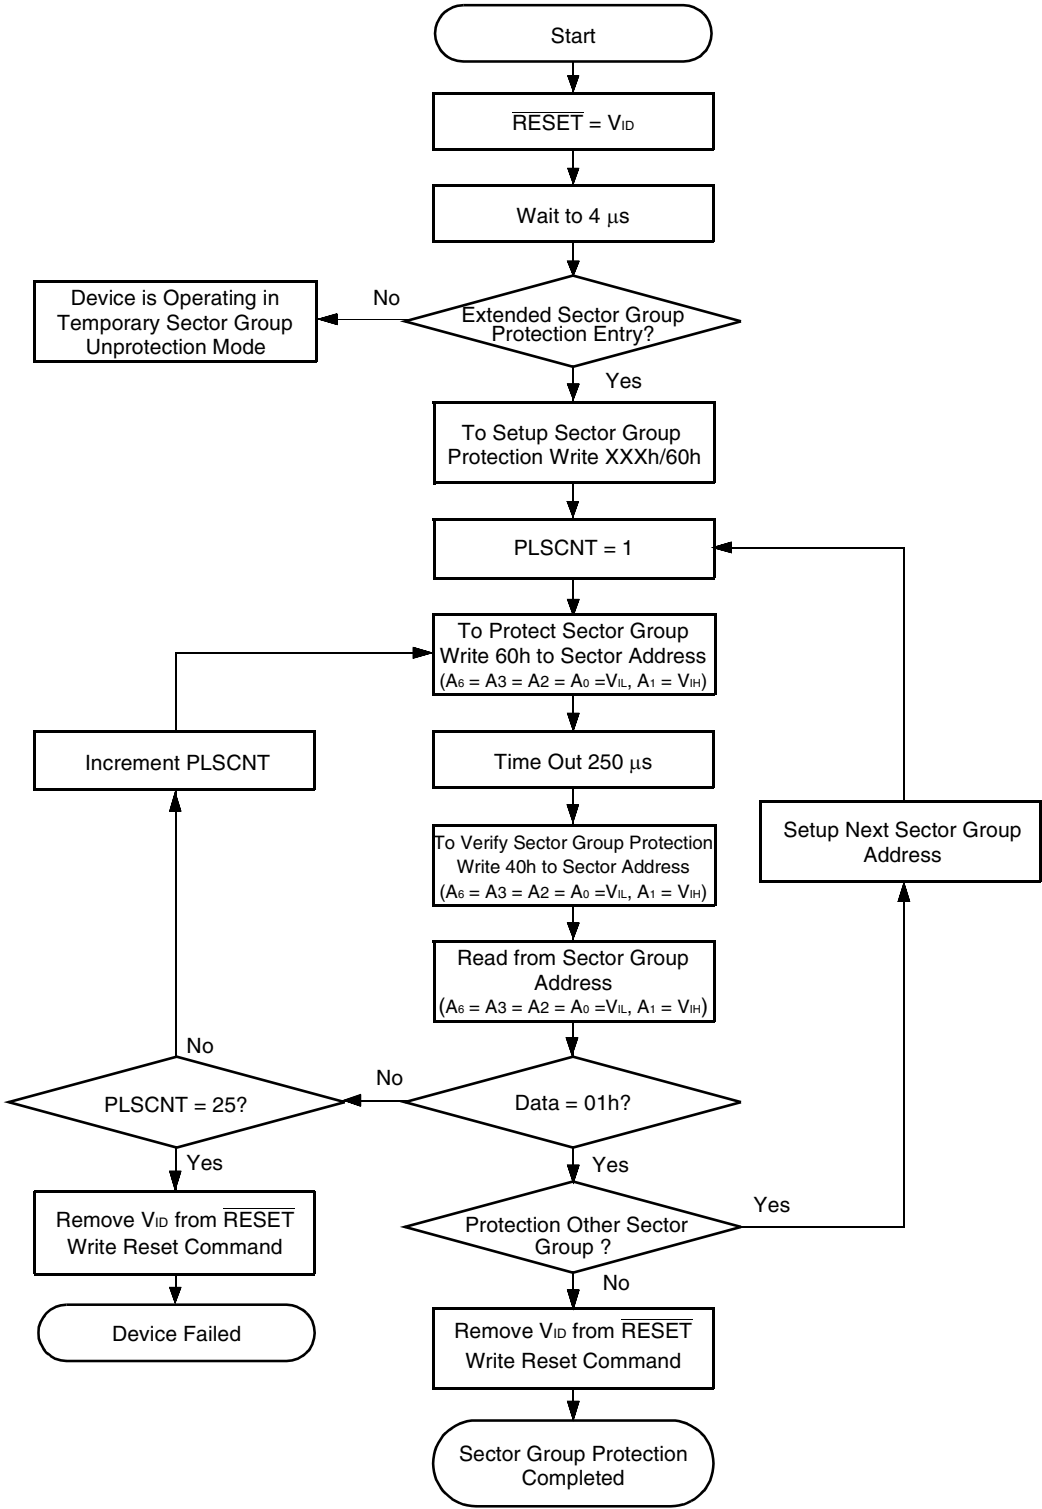

**Sector Group Protection Algorithm**

\*1 : All protected sector groups are unprotected.

\*2 : All previously protected sector groups are protected.

## Temporary Sector Group Unprotection Algorithm

Extended Sector Group Protection Algorithm

## FAST MODE ALGORITHM

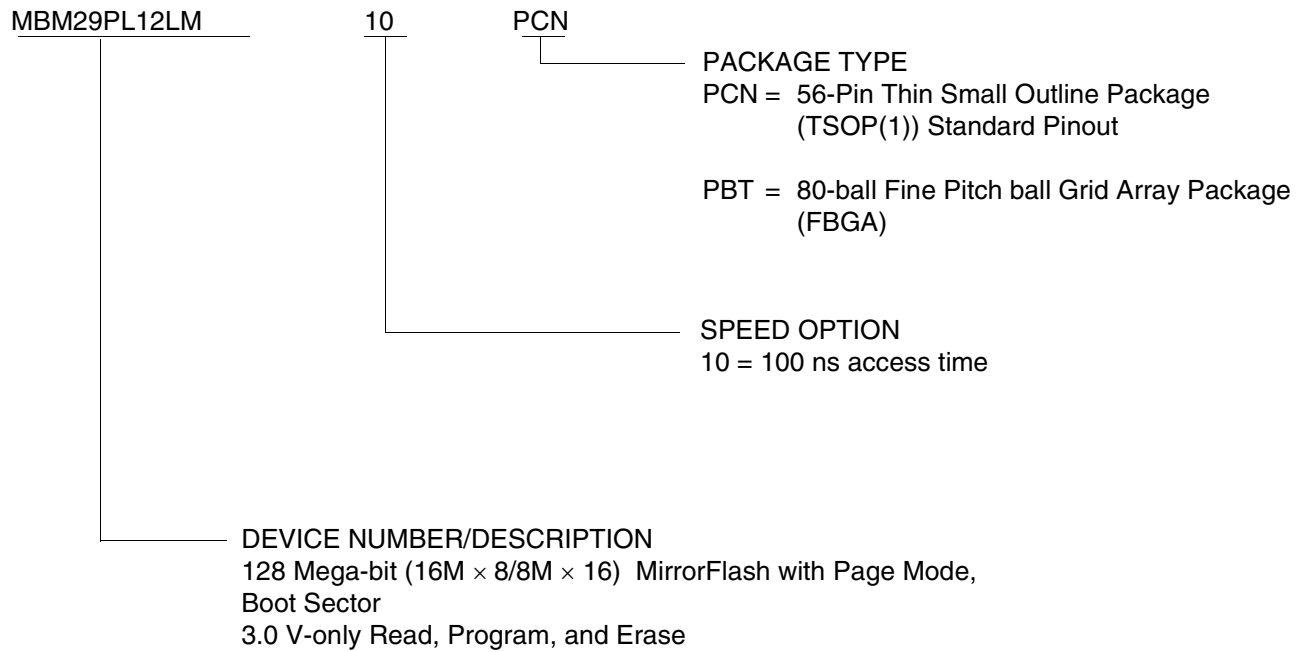

- Notes :
- The sequence is applied for Word ( × 16 ) mode.
  - The addresses differ from Byte ( × 8 ) mode.

The contents of this document are subject to change without notice. Customers are advised to consult with FUJITSU sales representatives before ordering.

The information, such as descriptions of function and application circuit examples, in this document are presented solely for the purpose of reference to show examples of operations and uses of Fujitsu semiconductor device; Fujitsu does not warrant proper operation of the device with respect to use based on such information. When you develop equipment incorporating the device based on such information, you must assume any responsibility arising out of such use of the information. Fujitsu assumes no liability for any damages whatsoever arising out of the use of the information.

Any information in this document, including descriptions of function and schematic diagrams, shall not be construed as license of the use or exercise of any intellectual property right, such as patent right or copyright, or any other right of Fujitsu or any third party or does Fujitsu warrant non-infringement of any third-party's intellectual property right or other right by using such information. Fujitsu assumes no liability for any infringement of the intellectual property rights or other rights of third parties which would result from the use of information contained herein.

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for use accompanying fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for use requiring extremely high reliability (i.e., submersible repeater and artificial satellite).

Please note that Fujitsu will not be liable against you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products.

Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.

If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the prior authorization by Japanese government will be required for export of those products from Japan.
