description

The TLV2544Q, TLV2548Q, and TLV2548M are a family of high performance, 12-bit low power, 3.5 μ s, CMOS analog-to-digital converters (ADC) which operate from a single 3-V to 5.5-V power supply. These devices have three digital inputs and a 3-state output [chip select (CS), serial input-output clock (SCLK), serial data input (SDI), and serial data output (SDO)] that provide a direct 4-wire interface to the serial port of most popular host microprocessors (SPI interface). When interfaced with a DSP, a frame sync (FS) signal is used to indicate the start of a serial data frame.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

3-V TO 5.5-V, 12-BIT, 200-KSPS, 4-/8-CHANNEL, LOW-POWER SERIAL ANALOG-TO-DIGITAL CONVERTERS WITH AUTOPOWER-DOWN

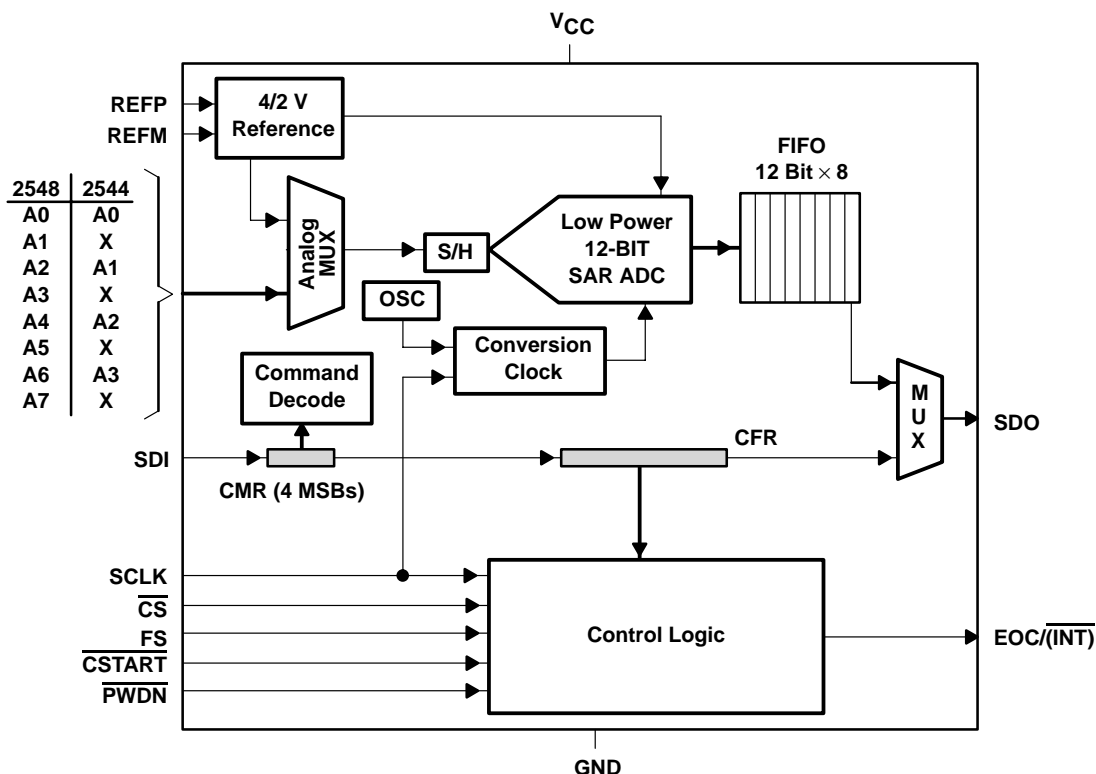

SGLS119C – FEBRUARY 2002 – REVISED OCTOBER 2002

description (continued)

In addition to a high-speed A/D converter and versatile control capability, these devices have an on-chip analog multiplexer that can select any analog inputs or one of three internal self-test voltages. The sample-and-hold function is automatically started after the fourth SCLK edge (normal sampling) or can be controlled by a special pin, $\overline{\text{CSTART}}$, to extend the sampling period (extended sampling). The normal sampling period can also be programmed as short (12 SCLKs) or as long (24 SCLKs) to accommodate faster SCLK operation popular among high-performance signal processors. The TLV2548 and TLV2544 are designed to operate with very low power consumption. The power-saving feature is further enhanced with software/hardware/autopower-down modes and programmable conversion speeds. The conversion clock (OSC) and reference are built-in. The converter can use the external SCLK as the source of the conversion clock to achieve higher (up to 2.8 μs when a 20 MHz SCLK is used) conversion speed. Two different internal reference voltages are available. An optional external reference can also be used to achieve maximum flexibility.

The TLV2544Q and the TLV2548Q are characterized for operation from -40°C to 125°C . The TLV2548M is characterized for operation from -55°C to 125°C .

Terminal Functions

| TERMINAL | | | | I/O | DESCRIPTION |
|--|----------------------|--|--|-----|--|
| NAME | NO. | | | | |
| | TLV2544 | TLV2548 | | | |
| A0 A1 A2 A3 A4 A5 A6 A7 | A0 A1 A2 A3 | 6 7 8 9 10 11 12 13 | 6 7 8 9 10 11 12 13 | I | Analog signal inputs. The analog inputs are applied to these terminals and are internally multiplexed. The driving source impedance should be less than or equal to 1 k Ω . For a source impedance greater than 1 k Ω , use the asynchronous conversion start signal $\overline{\text{CSTART}}$ ($\overline{\text{CSTART}}$ low time controls the sampling period) or program long sampling period to increase the sampling time. |
| $\overline{\text{CS}}$ | | 16 | 20 | I | Chip select. A high-to-low transition on the $\overline{\text{CS}}$ input resets the internal 4-bit counter, enables SDI, and removes SDO from 3-state within a maximum setup time. SDI is disabled within a setup time after the 4-bit counter counts to 16 (clock edges) or a low-to-high transition of $\overline{\text{CS}}$ whichever happens first. NOTE: $\overline{\text{CS}}$ falling and rising edges need to happen when SCLK is low for a microprocessor interface such as SPI. |
| $\overline{\text{CSTART}}$ | | 10 | 14 | I | This terminal controls the start of sampling of the analog input from a selected multiplex channel. Sampling time starts with the falling edge of $\overline{\text{CSTART}}$ and ends with the rising edge of $\overline{\text{CSTART}}$ as long as $\overline{\text{CS}}$ is held high. In mode 01, select cycle, $\overline{\text{CSTART}}$ can be issued as soon as CHANNEL is selected which means the fifth SCLK during the select cycle, but the effective sampling time is not started until $\overline{\text{CS}}$ goes to high. The rising edge of $\overline{\text{CSTART}}$ (when $\overline{\text{CS}} = 1$) also starts the conversion. Tie this terminal to V_{CC} if not used. |
| EOC/ $\overline{\text{INT}}$ | | 4 | 4 | O | End of conversion or interrupt to host processor. [PROGRAMMED AS EOC]: This output goes from a high-to-low logic level at the end of the sampling period and remains low until the conversion is complete and data are ready for transfer. EOC is used in conversion mode 00 only. [PROGRAMMED AS $\overline{\text{INT}}$]: This pin can also be programmed as an interrupt output signal to the host processor. The falling edge of $\overline{\text{INT}}$ indicates data are ready for output. The following $\overline{\text{CS}}\downarrow$ or $\overline{\text{FS}}$ clears $\overline{\text{INT}}$. |
| FS | | 13 | 17 | I | DSP frame sync input. Indication of the start of a serial data frame in or out of the device. If FS remains low after the falling edge of $\overline{\text{CS}}$, SDI is not enabled until an active FS is presented. A high-to-low transition on the FS input resets the internal 4-bit counter and enables SDI within a maximum setup time. SDI is disabled within a setup time after the 4-bit counter counts to 16 (clock edges) or a low-to-high transition of $\overline{\text{CS}}$ whichever happens first. Tie this terminal to V_{CC} if not used. NOTE: The current silicon will react to FS input irrespective of the state of $\overline{\text{CS}}$ signal. |
| GND | | 11 | 15 | I | Ground return for the internal circuitry. Unless otherwise noted, all voltage measurements are with respect to GND. |
| $\overline{\text{PWDN}}$ | | 12 | 16 | I | Both analog and reference circuits are powered down when this pin is at logic zero. The device can be restarted by active $\overline{\text{CS}}$, FS or $\overline{\text{CSTART}}$ after this pin is pulled back to logic one. |
| SCLK | | 3 | 3 | I | Input serial clock. This terminal receives the serial SCLK from the host processor. SCLK is used to clock the input SDI to the input register. When programmed, it may also be used as the source of the conversion clock. NOTE: This device supports CPOL (clock polarity) = 0, which is SCLK returns to zero when idling for SPI compatible interface. |
| SDI | | 2 | 2 | I | Serial data input. The input data is presented with the MSB (D15) first. The first 4-bit MSBs, D(15–12) are decoded as one of the 16 commands (12 only for the TLV2544). The configure write commands require an additional 12 bits of data. When FS is not used ($\text{FS} = 1$), the first MSB (D15) is expected after the falling edge of $\overline{\text{CS}}$ and is latched in on the rising edges of SCLK (after $\overline{\text{CS}}\downarrow$). When FS is used (typical with an active FS from a DSP) the first MSB (D15) is expected after the falling edge of FS and is latched in on the falling edges of SCLK. |

Terminal Functions (Continued)

| TERMINAL | | | I/O | DESCRIPTION |
|----------|---------|---------|-----|--|
| NAME | NO. | | | |
| | TLV2544 | TLV2548 | | |
| SDO | 1 | 1 | O | The 3-state serial output for the A/D conversion result. SDO is kept in the high-impedance state when \overline{CS} is high and after the \overline{CS} falling edge and until the MSB (D15) is presented. The output format is MSB (D15) first. When FS is not used (FS = 1 at the falling edge of \overline{CS}), the MSB (D15) is presented to the SDO pin after the \overline{CS} falling edge, and successive data are available at the rising edge of SCLK. When FS is used (FS = 0 at the falling edge of \overline{CS}), the MSB (D15) is presented to SDO after the falling edge of \overline{CS} and FS = 0 is detected. Successive data are available at the falling edge of SCLK. (This is typically used with an active FS from a DSP.) For conversion and FIFO read cycles, the first 12 bits are result from previous conversion (data) followed by 4 don't care bits. The first four bits from SDO for CFR read cycles should be ignored. The register content is in the last 12 bits. SDO is 3-state (float) after the 16th bit. |
| REFM | 14 | 18 | I | External reference input or internal reference decoupling. |
| REFP | 15 | 19 | I | External reference input or internal reference decoupling. (Shunt capacitors of 10 μ F and 0.1 μ F between REFP and REFM.) The maximum input voltage range is determined by the difference between the voltage applied to this terminal and the REFM terminal when an external reference is used. |
| VCC | 5 | 5 | I | Positive supply voltage |

detailed description

analog inputs and internal test voltages

The 4/8 analog inputs and three internal test inputs are selected by the analog multiplexer depending on the command entered. The input multiplexer is a break-before-make type to reduce input-to-input noise injection resulting from channel switching.

converter

The TLV2544/48 uses a 12-bit successive approximation ADC utilizing a charge redistribution DAC. Figure 1 shows a simplified version of the ADC.

The sampling capacitor acquires the signal on Ain during the sampling period. When the conversion process starts, the SAR control logic and charge redistribution DAC are used to add and subtract fixed amounts of charge from the sampling capacitor to bring the comparator into a balanced condition. When the comparator is balanced, the conversion is complete and the ADC output code is generated.

 Full scale code = FFFh, Vcode = VREFP – 1 LSB

control and timing

power up and initialization requirements

- Determine processor type by writing A000h to the TLV2544/48 (\overline{CS} must be toggled)
- Configure the device (\overline{CS} must make a high-to-low transition, then can be held low if in DSP mode; i.e., active FS.)

The first conversion after power up or resuming from power down is not valid.

start of the cycle:

- When FS is not used (FS = 1 at the falling edge of \overline{CS}), the falling edge of \overline{CS} is the start of the cycle.
- When FS is used (FS is an active signal from a DSP), the falling edge of FS is the start of the cycle.

first 4-MSBs: the command register (CMR)

The TLV2544/TLV2548 have a 4-bit command set (see Table 1) plus a 12-bit configuration data field. Most of the commands require only the first 4 MSBs, i.e., without the 12-bit data field.

NOTE:

The device requires a write CFR (configuration register) with 000h data (write A000h to the serial input) at power up to initialize host select mode.

The valid commands are listed in Table 1.

| 1110b | Eh | FIFO read, FIFO contents shown as SDO D(15–4), D(3–0) = 0000 | |
| 1111b | Fh plus data | Reserved | |

configuration

Configuration data is stored in one 12-bit configuration register (CFR) (see Table 2 for CFR bit definitions). Once configured after first power up, the information is retained in the H/W or S/W power down state. When the device is being configured, a write CFR cycle is issued by the host processor. This is a 16-bit write. If the SCLK stops after the first 8 bits are entered, then the next eight bits can be taken after the SCLK is resumed. The status of the CFR can be read with a read CFR command when the device is programmed for one-shot conversion mode (CFR D[6,5] = 00).

control and timing (continued)

Table 2. TLV2544/TLV2548 Configuration Register (CFR) Bit Definitions

| BIT | DEFINITION | |
|---------|---|--|
| D11 | Reference select 0: External 1: internal | |
| D10 | Internal reference voltage select 0: Internal ref = 4 V 1: internal ref = 2 V | |
| D9 | Sample period select 0: Short sampling 12 SCLKs (1x sampling time) 1: Long sampling 24 SCLKs (2x sampling time) | |
| D(8–7) | Conversion clock source select 00: Conversion clock = internal OSC 01: Conversion clock = SCLK 10: Conversion clock = SCLK/4 11: Conversion clock = SCLK/2 | |

† These bits only take effect in conversion modes 10 and 11.

sampling

The sampling period starts after the first 4 input data are shifted in if they are decoded as one of the conversion commands. These are select analog input (channel 0 through 7) and select test (channel 1 through 3).

normal sampling

When the converter is using normal sampling, the sampling period is programmable. It can be 12 SCLKs (short sampling) or 24 SCLKs (long sampling). Long sampling helps when SCLK is faster than 10 MHz or when input source resistance is high.

SGLS119C – FEBRUARY 2002 – REVISED OCTOBER 2002

extended sampling

$\overline{\text{CSTART}}$ – An asynchronous (to the SCLK) signal, via dedicated hardware pin, $\overline{\text{CSTART}}$, can be used in order to have total control of the sampling period and the start of a conversion. This extended sampling is user-defined and is totally independent of SCLK. While $\overline{\text{CS}}$ is high, the falling edge of $\overline{\text{CSTART}}$ is the start of the sampling period and is controlled by the low time of $\overline{\text{CSTART}}$. The minimum low time for $\overline{\text{CSTART}}$ should be at least equal to the minimum t_{SAMPLE} . In a select cycle used in mode 01 (REPEAT MODE), $\overline{\text{CSTART}}$ can be started as soon as the channel is selected (after the fifth SCLK). In this case the sampling period is not started until $\overline{\text{CS}}$ has become inactive. Therefore the nonoverlapped $\overline{\text{CSTART}}$ low time must meet the minimum sampling time requirement. The low-to-high transition of $\overline{\text{CSTART}}$ terminates the sampling period and starts the conversion period. The conversion clock can also be configured to use either internal OSC or external SCLK. This function is useful for an application that requires:

- The use of an extended sampling period to accommodate different input source impedance
- The use of a faster I/O clock on the serial port but not enough sampling time is available due to the fixed number of SCLKs. This could be due to a high input source impedance or due to higher MUX ON resistance at lower supply voltage.

Once the conversion is complete, the processor can initiate a read cycle by using either the read FIFO command to read the conversion result or by simply selecting the next channel number for conversion. Since the device has a valid conversion result in the output buffer, the conversion result is simply presented at the serial data output. To completely get out of the extended sampling mode, $\overline{\text{CS}}$ must be toggled twice from a high-to-low transition while $\overline{\text{CSTART}}$ is high. The read cycle mentioned above followed by another configuration cycle of the ADC qualifies this condition and will successfully put the ADC back to its normal sampling mode. This can be viewed in Figure 9.

Table 3. Sample and Convert Conditions

| | CONDITIONS | SAMPLE | CONVERT |
|----------------------------|--|--|---|
| $\overline{\text{CSTART}}$ | $\overline{\text{CS}} = 1$ | No sampling clock (SCLK) required. Sampling period is totally controlled by the low time of $\overline{\text{CSTART}}$. The high-to-low transition of $\overline{\text{CSTART}}$ (when $\overline{\text{CS}}=1$) starts the sampling of the analog input signal. The low time of $\overline{\text{CSTART}}$ dictates the sampling period. The low-to-high transition of $\overline{\text{CSTART}}$ ends sampling period and begins the conversion cycle. (Note: this trigger only works when internal reference is selected for conversion modes 01, 10, and 11.) | 1) If internal clock OSC is selected a minimum of 3 MHz (equivalent to 4.6 μs conversion speed) can be achieved. 2) If external SCLK is selected, conversion time is $t_{\text{conv}} = 14 \times \text{DIV}/f(\text{SCLK})$, where DIV can be 1, 2, or 4. |
| $\overline{\text{CS}}$ | $\overline{\text{CSTART}} = 1$ $\text{FS} = 1$ | SCLK is required. Sampling period is programmable under normal sampling. When programmed to sample under short sampling, 12 SCLKs are generated to complete sampling period. 24 SCLKs are generated when programmed for long sampling. A command set to configure the device requires 4 SCLKs thereby extending to 16 or 28 SCLKs respectively before conversion takes place. (Note: Because the ADC only bypasses a valid channel select command, the user can use <i>select channel 0, 0000b</i> , as the SDI input when either $\overline{\text{CS}}$ or FS is used as trigger for conversion. The ADC responds to commands such as SW power-down, 1000b.) | |
| FS | $\overline{\text{CSTART}} = 1$ $\overline{\text{CS}} = 0$ | | |

TLV2544/TLV2548 conversion modes

The TLV2544 and TLV2548 have four different conversion modes (mode 00, 01, 10, 11). The operation of each mode is slightly different, depending on how the converter performs the sampling and which host interface is used. The trigger for a conversion can be an active $\overline{\text{CSTART}}$ (extended sampling), $\overline{\text{CS}}$ (normal sampling, SPI interface), or FS (normal sampling, TMS320 DSP interface). When FS is used as the trigger, $\overline{\text{CS}}$ can be held active, i.e. $\overline{\text{CS}}$ does not need to be toggled through the trigger sequence. SDI can be one of the channel select commands, such as SELECT CHANNEL 0. Different types of triggers should not be mixed throughout the repeat and sweep operations. When $\overline{\text{CSTART}}$ is used as the trigger, the conversion starts on the rising edge of $\overline{\text{CSTART}}$. The minimum low time for $\overline{\text{CSTART}}$ is equal to t_{SAMPLE} . If an active $\overline{\text{CS}}$ or FS is used as the trigger, the conversion is started after the 16th or 28th SCLK edge. Enough time (for conversion) should be allowed between consecutive triggers so that no conversion is terminated prematurely.

one shot mode (mode 00)

One shot mode (mode 00) does not use the FIFO, and the EOC is generated as the conversion is in progress (or $\overline{\text{INT}}$ is generated after the conversion is done).

repeat mode (mode 01)

Repeat mode (mode 01) uses the FIFO. This mode setup requires configuration cycle and channel select cycle. Once the programmed FIFO threshold is reached, the FIFO must be read, or the data is lost when the sequence starts over again with the SELECT cycle and series of triggers. No configuration is required except for reselecting the channel unless the operation mode is changed. This allows the host to set up the converter and continue monitoring a fixed input and come back to get a set of samples when preferred.

Triggered by $\overline{\text{CSTART}}$: The first conversion can be started with a select cycle or $\overline{\text{CSTART}}$. To do so, the user can issue $\overline{\text{CSTART}}$ during the select cycle, immediately after the four-bit channel select command. The first sample started as soon as the select cycle is finished (i.e., $\overline{\text{CS}}$ returns to 1). If there is enough time (2 μs) left between the SELECT cycle and the following $\overline{\text{CSTART}}$, a conversion is carried out. In this case, you will need one less trigger to fill the FIFO. Succeeding samples are triggered by $\overline{\text{CSTART}}$.

sweep mode (mode 10)

Sweep mode (mode 10) also uses the FIFO. Once it is programmed in this mode, all of the channels listed in the selected sweep sequence are visited in sequence. The results are converted and stored in the FIFO. This sweep sequence may not be completed if the FIFO threshold is reached before the list is completed. This allows the system designer to change the sweep sequence length. Once the FIFO has reached its programmed threshold, an interrupt ($\overline{\text{INT}}$) is generated. The host must issue a read FIFO command to read and clear the FIFO before the next sweep can start.

repeat sweep mode (mode 11)

Repeat sweep mode (mode 11) works the same way as mode 10 except the operation has an option to continue even if the FIFO threshold is reached. Once the FIFO has reached its programmed threshold, an interrupt ($\overline{\text{INT}}$) is generated. Then two things may happen:

1. The host may choose to act on it (read the FIFO) or ignore it. If the next cycle is a read FIFO cycle, all of the data stored in the FIFO is retained until it has been read in order.
2. If the next cycle is not a read FIFO cycle, or another $\overline{\text{CSTART}}$ is generated, all of the content stored in the FIFO is cleared before the next conversion result is stored in the FIFO, and the sweep is continued.

| | | Extended | <ul style="list-style-type: none"> Same as normal sampling except \overline{CSTART} starts each sampling and conversion when \overline{CS} is high. |

NOTES: 1. Programming the $\overline{EOC}/\overline{INT}$ pin as the \overline{EOC} signal works for mode 00 only. The other three modes automatically generate an \overline{INT} signal irrespective of how $\overline{EOC}/\overline{INT}$ is programmed.
2. When using \overline{CSTART} to sample in extended mode, the falling edge of the next \overline{CSTART} trigger should occur no more than 2.5 μ s after the falling \overline{CS} edge (or falling \overline{FS} edge if \overline{FS} is active) of the channel select cycle. This is to prevent an ongoing conversion from being canceled.

timing diagrams

The timing diagrams can be categorized into two major groups: nonconversion and conversion. The nonconversion cycles are read and write (configuration). None of these cycles carry a conversion. Conversion cycles are those four modes of conversion.

read cycle (read FIFO or read CFR)

read CFR cycle:

The read command is decoded in the first 4 clocks. SDO outputs the contents of the CFR after the 4th SCLK.

SGLS119C – FEBRUARY 2002 – REVISED OCTOBER 2002

read cycle (read FIFO or read CFR) (continued)

FIFO read cycle

The first command in the active cycle after $\overline{\text{INT}}$ is generated, if the FIFO is used, is assumed as the FIFO read command. The first FIFO content is output immediately before the command is decoded. If this command is not a FIFO read, then the output is terminated but the first data in the FIFO is retained until a valid FIFO read command is decoded. Use of more layers of the FIFO reduces the time taken to read multiple data. This is because the read cycle does not generate EOC or $\overline{\text{INT}}$, nor does it carry out any conversion.

write cycle (write CFR)

The write cycle is used to write to the configuration register CFR (with 12-bit register content). The write cycle does not generate an EOC or $\overline{\text{INT}}$, nor does it carry out any conversion (see power up and initialization requirements).

FIFO operation

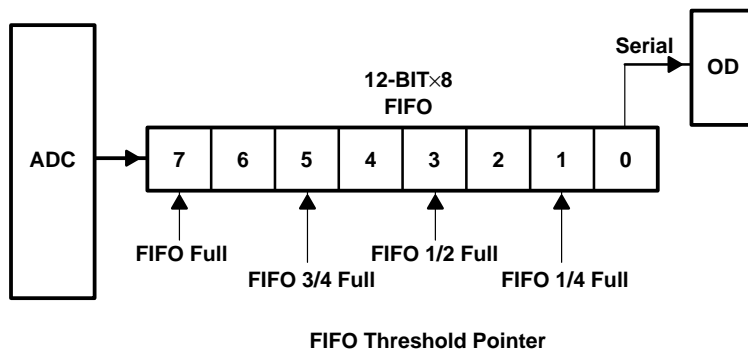

Figure 15. TLV2544/TLV2548 FIFO

The device has an 8-layer FIFO that can be programmed for different thresholds. An interrupt is sent to the host after the preprogrammed threshold is reached. The FIFO can be used to store data from either a fixed channel or a series of channels based on a preprogrammed sweep sequence. For example, an application may require eight measurements from channel 3. In this case, the FIFO is filled with eight data sequentially taken from channel 3. Another application may require data from channel 0, channel 2, channel 4, and channel 6 in an orderly manner. Therefore, the threshold is set for 1/2 and the sweep sequence 0–2–4–6–0–2–4–6 is chosen. An interrupt is sent to the host as soon as all four data are in the FIFO.

In single shot mode, the FIFO automatically uses a 1/8 FIFO depth. Therefore the CFR bits (D1,0) controlling FIFO depth are *don't care*.

SCLK and conversion speed

There are two ways to adjust the conversion speed.

- The SCLK can be used as the source of the conversion clock.

The onboard OSC is approximately 4 MHz and 14 conversion clocks are required to complete a conversion. (Corresponding 3.5 μs conversion time) The devices can operate with an SCLK up to 20 MHz for the supply voltage range specified. When a more accurate conversion time is desired, the SCLK can be used as the source of the conversion clock. The clock divider provides speed options appropriate for an application where a high speed SCLK is used for faster I/O. The total conversion time is $14 \times (DIV/f_{SCLK})$ where DIV is 1, 2, or 4. For example a 20 MHz SCLK with the divide by 4 option produces a $\{14 \times (4/20 M)\} = 2.8 \mu s$ conversion time. When an external serial clock (SCLK) is used as the source of the conversion clock, the maximum equivalent conversion clock (f_{SCLK}/DIV) should not exceed 6 MHz.

- Autopower down can be used. This mode is always on. If the device is not accessed (by \overline{CS} or \overline{CSTART}), the converter is powered down to save power. The built-in reference is left on in order to quickly resume operation within one half SCLK period. This provides unlimited choices to trade speed with power savings.

reference voltage

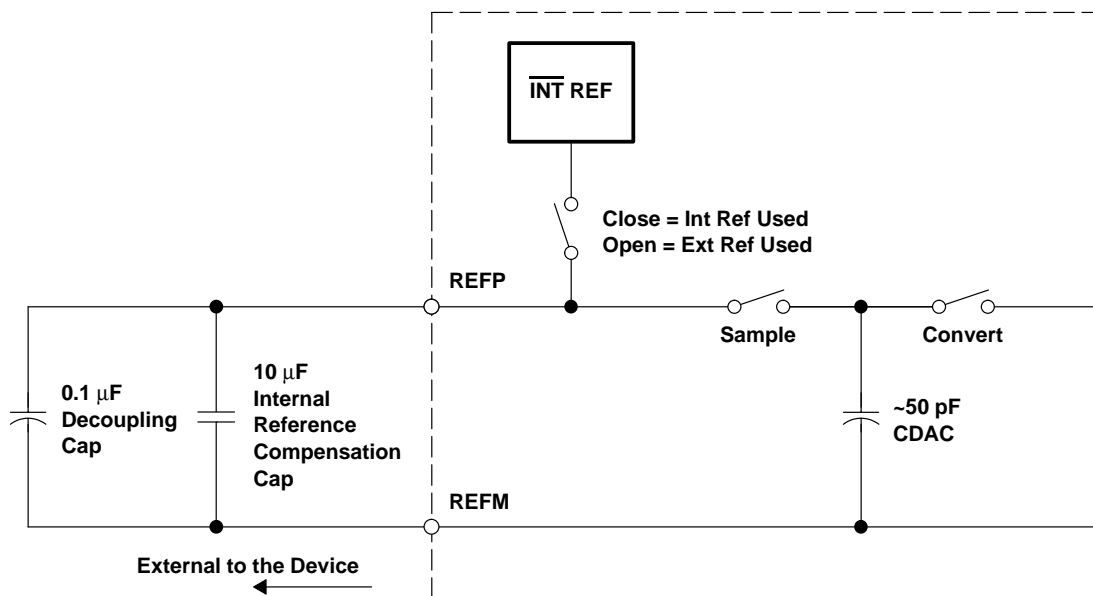

The device has a built-in reference with a programmable level of 2 V or 4 V. If the internal reference is used, REFP is set to 2 V or 4 V and REFM is set to 0 V. An external reference can also be used through two reference input pins, REFP and REFM, if the reference source is programmed as external. The voltage levels applied to these pins establish the upper and lower limits of the analog inputs to produce a full-scale and zero-scale reading respectively. The values of REFP, REFM, and the analog input should not exceed the positive supply or be lower than GND consistent with the specified absolute maximum ratings. The digital output is at full scale when the input signal is equal to or higher than REFP and at zero when the input signal is equal to or lower than REFM.

SGLS119C – FEBRUARY 2002 – REVISED OCTOBER 2002

reference block equivalent circuit

- NOTES:
- A. If internal reference is used, tie REF_{FM} to AGND and install a 10 μF (or 4.7 μF) internal reference compensation capacitor between REF_{FP} and REF_{FM} to store the charge as shown in the figure above.
 - B. If external reference is used, the 10 μF (internal reference compensation) capacitor is optional. REF_{FM} can be connected to external REF_{FM} or AGND.
 - C. Internal reference voltage drift, due to temperature variations, is approximately ±10 mV about the nominal 2 V (typically) from –10°C to 100°C. The nominal value also varies approximately ±50 mV across devices.
 - D. Internal reference leakage during low ON time: Leakage resistance is on the order of 100 MΩ or more. This means the time constant is about 1000 s with 10 μF compensation capacitance. Since the REF voltage does not vary much, the reference will come up quickly after resuming from auto power down. At power up and power down the internal reference sees a glitch of about 500 μV when 2 V internal reference is used (1 mV when 4 V internal reference is used). This glitch settles out after about 50 μs.

power down

Writing 8000h to the device puts the device into a software power down state. For a hardware power-down, the dedicated $\overline{\text{PWDN}}$ pin provides another way to power down the device asynchronously. These two power-down modes power down the entire device including the built-in reference to save power. It requires 20 ms to resume from either a software or hardware power down.

Auto power-down mode is always enabled. This mode maintains the built-in reference if an internal reference is used so resumption is fast enough to be used between cycles.

The configuration register is not affected by any of the power down modes but the sweep operation sequence has to be started over again. All FIFO contents are cleared by the power-down modes.

operating characteristics over recommended operating free-air temperature range, $V_{CC} = V_{REFP}$
 $= 3\text{ V to }5.5\text{ V}$, SCLK frequency = 20 MHz (unless otherwise noted)

| PARAMETER | | TEST CONDITIONS | MIN | TYP† | MAX | UNIT | | |
|--|---|---|--|--|--|-----------|---------------|------|
| E_L | Integral linearity error (INL) (see Note 5) | | | | ± 1.2 | LSB | | |
| E_D | Differential linearity error (DNL) | See Note 4 | | | ± 1 | LSB | | |
| E_O | Offset error (see Note 6) | See Note 4 | Q Suffix | | ± 2 | LSB | | |
| | | | M Suffix, $T_A = 25^\circ\text{C}$ and 125°C | -4 | +6 | | | |
| | | | M Suffix, $T_A = -55^\circ\text{C}$ | -4 | +6.2 | | | |
| E_{FS} | Full scale error (see Note 6) | See Note 4 | Q Suffix | | ± 1.1 | ± 4 | LSB | |
| | | | | M Suffix, $T_A = 25^\circ\text{C}$ and 125°C | -4 | ± 1.1 | | +6 |
| | | | | M Suffix, $T_A = -55^\circ\text{C}$ | -4 | ± 1.1 | | +7.6 |
| Self-test output code (see Table 1 and Note 7) | | SDI = B000h | | | 800h (2048D) | | | |
| | | SDI = C000h | | | 000h (0D) | | | |
| | | SDI = D000h | | | FFFh (4095D) | | | |
| $t_{(conv)}$ | Conversion time | Internal OSC | OSC = 3 MHz to 6 MHz | | 3.2 | 4.65 | μs | |
| | | External SCLK | | | $\frac{(14 \times \text{DIV})}{f_{\text{SCLK}}}$ | | | |
| $t_{(sample)}$ | Sampling time | With a maximum of 1-k Ω input source impedance | | | 600 | ns | | |

† All typical values are at $T_A = 25^\circ\text{C}$.

- NOTES: 4. Analog input voltages greater than that applied to REFP convert as all ones (1111111111), while input voltages less than that applied to REFM convert as all zeros (0000000000).
5. Linear error is the maximum deviation from the best straight line through the A/D transfer characteristics.
6. Zero error is the difference between 0000000000 and the converted output for zero input voltage: full-scale error is the difference between 1111111111 and the converted output for full-scale input voltage.
7. Both the input data and the output codes are expressed in positive logic.

PARAMETER MEASUREMENT INFORMATION

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.
